^{*} The computation was carried out by G. W. Reitwiesner on ENIAC using a total of 70 hours of machine running time in July 1949 using the formula $\pi/4 = 4$ arc tan 1/5—arc tan 1/239 in conjunction with the Gregory series

are
$$\tan x = \sum_{n=0}^{\infty} (-1)^n (2n+1)^{-1} x^{2n+1}$$
.

It would be of interest to apply tests of randomness on the decimal digits upto 500, 1000, 1500, 2000 places. For instance, the frequencies of 0, 1, ..., 9 in the first 2000 decimals are

182, 212, 207, 189, 195, 205, 200, 197, 202, 211

which are all close to expected 200. (Apply chi-square tests).

PREFACE

1.

The present volume had its origin mainly in the recognition of a need repeatedly brought up by our students and colleagues, as well as by a number of professional statisticians and research workers engaged in various applied fields, for a handbook which is not merely a collection of mathematical and statistical tables but which contains reference material that will aid memory and offer guidance on various points of statistical theory and practice. With this end in view we started on a project some years ago, and have since evolved and incorporated in this volume a method of presenting formulae and tables so as to offer a great facility in their use for statistical data analysis.

Part I of this volume entitled "General Notes and Formulae" provides a fairly comprehensive but selected set of formulae together with brief explanations, under the following heads: (I) moments and cumulants, (II) discrete and (III) continuous distributions, (IV) standard errors, (V) sample survey estimates and standard errors, and (VI) numerical analysis. The formulae, together with related notes, will be found to be a collection in one place of what are usually scattered in different text books, or other sources, and of what are usually required for statistical applications. In the presentation of the material in this section, special attempts have been made to highlight certain aspects (such as the use of interpolation formulae) which the authors have considered important and, at the same time, which have not been adequately discussed elsewhere. The list of discrete distributions given in Part I would be of interest to even research workers in theoretical statistics. In the presentation of the formulae and notes, emphasis has been placed on furnishing necessary guidelines for practical use rather than derivations of proofs.

The sixtyseven tables given in Part II of the volume fall under two broad categories: firstly tables associated with probability distributions and relating directly to tests of significance and other analytic statistical methods, and secondly, tables which find direct use in the processing of statistical data.

A special feature in the presentation of these tables is that, before each table, an explanatory note, giving a description of the table and containing illustrative examples, is provided. Where necessary, the type of formulae to be used for interpolation in the tables and the accuracy attainable are also indicated. Where the nature of interpolation is not indicated, in general, it could be assumed that linear interpolation would suffice. In the explanatory note on each table, a section is devoted to give references to other available publications containing more extensive tables.

Some of the special features of the section on tables are: i) a table of interpolation co-efficients, ii) an expanded table of numerical integration co-efficients, iii) percentage points of the beta distribution so as to give directly the significant

values of the multiple correlation co-efficient, iv) expanded tables for angular transformation of the binomial proportion and z-transformation of the correlation co-efficient, v) a comparatively extensive table of the normal distribution, vi) mathematical tables of a wide variety, vii) tables to facilitate conversion of number systems for special use in programming for electronic computers, viii) a handy arrangement of control chart factors, ix) a collection of tables for lot quality estimation, x) a simplified set of lot acceptance sampling inspection tables, xi) random permutations of digits and random numbers, etc.

It is hoped that the collection of tables and formulae, together with associated notes in this volume, will form a fairly adequate and handy aid to professional statisticians, research workers and others who have to deal with problems involving statistical analysis and inference.

Notation

In Part I (General Notes and Formulae), Roman numerals (I, II,.....) are used to number the chapters and lower case Latin alphabet (a, b,.....) for sections. Thus, a reference such as IIb means section b in chapter II of Part I.

In Part II (Tables with Explanatory Notes), the chapters are numbered as 1, 2,; sections as 1, 2,, and subsections as a, b, Thus a reference such as 15.2b means the subsection b in section 2 of chapter 15. When a Chapter does not contain sections, references to subsections are made such as 19c, i.e., subsection c in Chapter 19. Tables in a chapter are numbered serially; thus, Table 13.2 stands for the second table in chapter 13 of Part II.

Calcutta, India June, 1966

C. R. RAO S. K. MITRA A. MATTHAI

Preface to Second Edition

A number of new tables and explanatory notes useful in Statistical Quality Control (SQC) have been added (W test for normality, tests for outliers, probability plotting, CUSUM charts, tolerance intervals, distribution of ranges etc.). Tables of sampling plans are withdrawn. It is hoped to bring out a separate publication for these tables. The values of π and e are given upto 2035 and 2500 decimal places respectively.

Acknowledgements

We are indebted to many of our colleagues in the Indian Statistical Institute for help rendered to us at different stages in the preparation of the "Formulae and Tables". We are specially thankful to Dr. B. Ramachandran and Shri T. S. Krishnan for their help in the final stages of publication, and to Dr. Jogabrata Rey for help in using the various computational and other facilities at the Institute which have made our task relatively less burdensome and accounted for its early completion.

In compiling the numerous statistical and mathematical tables, we have made use of journals, books and other published and unpublished sources, which we gratefully acknowledge here.

We are indebted to the late Sir Ronald A. Fisher, F.R.S., Cambridge and Dr. Frank Yates, F.R.S., Rothamsted, and also to Messrs. Oliver and Boyd Ltd., Edinburgh, for permission to reprint Table I (The normal distribution), Table XXIII (Orthogonal polynomials), Table XV (Latin squares) and Table XVI (Complete sets of orthogonal latin squares), and Table XX (Scores for ordinal or ranked data) from Statistical Tables for Biological, Agricultural and Medical Research.

We are indebted to Professor E. S. Pearson and Dr. H. O. Hartley for permission to reprint Table 18 (Percentage points of the F distribution), Table 24 (Percentage points of the extreme standardised deviate from the population mean), Table 26 (Percentage points of the extreme Studentised deviate from the sample mean) and Table 31 (Percentage points of the ratio s_{max}^2/s_{min}^2), from Biometrika Tables for Statisticians, Vol. 1.

We are indebted to the Indian Standards Institution for permission to reprint the acceptance sampling plans from their bulletin IS: 2500 (Part I)—1963: Sampling Inspection Tables.

We owe a special debt of gratitude to the Statistical Publishing Society, Calcutta, for the keen interest they have shown in the publication of the "Formulae and Tables" and to the Eka Press, Calcutta, for the promptness and accuracy with which they have printed this volume.

PART I

I. MOMENTS AND CUMULANTS

a. Relation between raw moments (μ_r) and central moments (μ_r)

For a distribution function F(x) let $\mu'_r = \int_{-\infty}^{\infty} (x-c)^r dF$ and $\mu_r = \int_{-\infty}^{\infty} (x-m)^r dF$ where $m = \int_{-\infty}^{\infty} x dF$ is the mean value and c is an arbitrary origin. Then

$$\mu_r = \mu_r' - r\mu_{r-1}' \mu_1 + \binom{r}{2} \mu_{r-2}' \mu_{1}'^2 + \cdots + (-1)^{r-1} (r-1) \mu_1''.$$

Thus,

$$\begin{split} \mu_2 &= \mu_2' - \mu_1'^2 \\ \mu_3 &= \mu_3' - 3\mu_2'\mu_1' + 2\mu_1'^3 \\ \mu_4 &= \mu_4' - 4\mu_3'\mu_1' + 6\mu_2'\mu_1'^2 - 3\mu_1'^4 . \end{split}$$

b. Relation between factorial moments and raw moments

The r-th factorial moment about an arbitrary origin c is defined by

$$\mu'_{[r]} = \int_{-\infty}^{\infty} (x-c)(x-c-h) \cdot \cdot \cdot (x-c-rh+h)dF.$$

If μ'_r be raw moments also about the same origin c, we have the following relations between the factorial and the raw moments.

factorial moments	in terms of raw moments	raw moments	in terms of factorial moments
$\mu'_{[1]}$	μ_1'	μ_1'	$\mu_{[1]}^{'}$
$\mu_{[2]}^{\prime}$	$\mu_2'-h\mu_1'$	/l'2	$\mu_{[2]}^{'} + h \mu_{[1]}^{'}$
$\mu_{[3]}^{\prime}$.	$\mu_3' - 3h\mu_2' + 2h^2\mu_1'$	//3	$\mu'_{[3]} + 3h\mu'_{[2]} + h^2\mu'_{[1]}$
µ'[4]	$\mu_4'\!-\!6h\mu_3'\!+\!11h^2\mu_2'\!-\!6h^3\mu_1'$	μ_4'	$\mu'_{[4]} + 6h\mu'_{[3]} + 7h^2\mu'_{[2]} + h^3\mu'_{[1]}$

c. Relation between cumulants and moments

Cumulants are formally defined by the identity

$$\exp\Bigl\{\kappa_1 t + \frac{\kappa_2 t^2}{2!} + \frac{\kappa_3 t^3}{3!} + \ldots\Bigr\} = 1 + \mu_1' t + \mu_2' \ \frac{t^2}{2!} \ + \mu_3' \ \frac{t^3}{3!} \ + \ldots$$

From the definition it follows that the cumulants, except for the first, are invariant for change of origin.

cumulants	in terms of moments	moments	in terms of Sumulants
κ ₁	μ_1	μ_1'	κ_1
κ2	μ_{2}	μ_2	κ ₂
κ _{3,}	μ_3	μ_3	κ_3
κ_{4}	μ_4 – $3\mu_{\tilde{z}}^2$	μ_4	$\kappa_4 + 3\kappa_2^2$
κ_5	$\mu_5 - 10 \mu_3 \mu_2$	μ_5	$\kappa_5 + 10 \kappa_3 \kappa_2$
κ ₆ .	$\mu_6 \!-\! 15 \mu_4 \mu_2 \!-\! 10 \mu_3^2 \!+\! 30 \mu_2^3$	μ_{6}	$\kappa_6 + 15 \kappa_4 \kappa_2 + 10 \kappa_3^2 + 15 \kappa_2^3$

d. Probability and moment generating functions

For a discrete distribution assigning probabilities p_0, p_1, p_2, \dots to variable values $0, 1, 2, \dots$ consider the following generating functions:

(i) the probability generating function (pgf)

$$P(t) = \sum_{i=0}^{\infty} p_i t^i,$$

(ii) the factorial moment generating function (fmgf)

$$M_f(t) = \sum_{i=0}^{\infty} \mu'_{[i]} t^i / i!$$

where for the factorial moments $\mu_{[i]}$ the origin c=0 and h=1, and

(iii) the moment generating function (mgf)

$$M(t) = \sum_{i=0}^{\infty} \mu_i t^i / i!$$

where for the raw moments μ_i the origin c=0

We have here the relations

$$M_f(t) = P(1+t), M(t) = P(e^t)$$

e. Sheppard's correction for grouping

For a distribution function F(x) the proportion of observations in an interval $(a_i, a_{i+1}]$ is given by

$$\pi_i = \int_{a_i}^{a_{i+1}} dF$$

Let the system of intervals $(a_i, a_{i+1}]$ for $i = 0, \pm 1, \pm 2, \ldots$ cover the entire range of the distribution. Consider the grouped frequency distribution with variate values $b_i = \frac{a_i + a_{i+1}}{2}$ and relative frequencies π_i . The r-th raw moment of the grouped frequency distribution is represented by $\overline{\mu}'_r = \sum_{i=-\infty}^{\infty} (b_i - c)^r \pi_i$. Cumulants and

factorial moments calculated from the grouped frequency distribution will be similarly indicated by $\bar{\kappa}_r$ and $\bar{\mu}'_{[r]}$ respectively.

Consider the case where intervals are of equal width h and the distribution admits a density function f(x) Assume further that: (a) f(x) and its first 2s derivatives are continuous for all x, (b) x^{k+2} $\frac{d^i f(x)}{dx^i}$ is bounded for all x and for i=0,1,2,...,2s, where k and s are certain positive integers. Under these conditions for all $r \leqslant k$

(i)
$$\mu'_{r} = \sum_{j=0}^{r} {r \choose j} (2^{1-j}-1)B_{j}h^{j}\mu'_{r-j} + R$$

(ii) $\mu'_{[r]} = \sum_{j=0}^{r} {r \choose j} B_{j}^{(j+2)} \left(\frac{3}{2}\right) h^{j}\overline{\mu}'_{[r-j} + R$
(iii) $\kappa_{2r-1} = \kappa_{2r-1} + R$
 $\kappa_{2r} = \overline{\kappa}_{2r} - B_{2r} \frac{h^{2r}}{2r} + R$

where B_j 's are the Bernoulli numbers tabulated in table 17.9 and the Bernoulli polynomial $B_j^{(j+2)}$ (3/2) is equal to

$$\frac{(-1)^{j+1}(2j)!}{2^{2j}(j+1)!} \; \Big(\frac{1}{3} + \frac{1}{5} + \ldots + \frac{1}{2j-1}\Big) \text{for } j > 1,$$

 $B_0^{(2)}\left(\frac{3}{2}\right)=1,$ $B_1^{(3)}\left(\frac{3}{2}\right)=0.$ The remainder term R in each case is of the order $O(h^{2s})$.

Whenever the frequency curve y = f(x) has a contact of high order at the extremities, conditions (a) and (b) are usually satisfied for moderate values of s and k. In such cases it has been found in practice that the result of applying the corrections is usually good even when h is not small. Putting r = 1, 2, ... and ignoring R we have the following Sheppard's corrections for the moments, factorial moments and cumulants.

· · · · · · · · · · · · · · · · · · ·		
mean and central moments	factorial moments	cumulants
$\mu_1' = \overline{\mu_1'}$	$\mu'_{[1]} = \overline{\mu}'_{[1]}$	$ \kappa_i = \vec{\kappa}_1 $
$\mu_2=\overline{\mu}_2-rac{1}{12}h^2$	$\mu'_{[2]} = \overline{\mu}'_{[2]} - \frac{h^3}{12}$	$\kappa_2 = \overline{\kappa}_2 - \frac{\hbar^2}{12}$
$\mu_3 = \overline{\mu}_3$ $= 1 - 10 7 14$	$\mu_{[3]} = \overline{\mu}_{3}' - \frac{h^{2}}{4}\overline{\mu}_{[1]}' + \frac{h^{3}}{4}$	$\kappa_3 = \overline{\kappa}_3$
$\mu_4 = \overline{\mu}_4 - \frac{1}{2} \overline{\mu}_2 h^2 + \frac{7}{240} h^4$	$\mu_{[4]} = \overline{\mu}_{[4]}' - \frac{h^2}{2} \overline{\mu}_{[2]}' + h^3 \overline{\mu}_{[1]}'$	$\kappa_4 = \overline{\kappa}_4 + \frac{h^4}{120}$
$\mu_5=\overline{\mu}_5-rac{5}{6}~\overline{\mu}_3h^2$	$-\frac{71}{80}h^4$	$\kappa_5 = \overline{\kappa}_5$ $\kappa_6 = \overline{\kappa}_8 - \frac{h^6}{252}$
$\mu_6 = \overline{\mu}_6 - \frac{5}{4} \overline{\mu}_4 h^2 + \frac{7}{16} \overline{\mu}_2 h^4$		292
$-\frac{31}{1344}h^6$		

II DISCRETE DISTRIBUTIONS

The tables of discrete distributions give the mean and variance in addition to the mgf, M(t) Higher raw moments can be obtained by differentiating the cgf, $K(t) = \log_e M(t)$. Thus $\kappa_r = \frac{d^r K}{dt^r}$ The pgf, $P(t) = M(\log_e t)$. The

probability of x is $\frac{1}{x!} \frac{dxP}{dt^2}$

b. Some non-central distributions (density functions)

(i) Bivariate normal (with means μ_1 , μ_2 ; variances σ_1^2 , σ_2^2 and correlation ρ)

$$\begin{split} N_2(x_1,\,x_2\,|\,\mu_1,\,\mu_2;\,\sigma_1,\,\sigma_2,\rho) \\ &= (2\pi\sigma_1\sigma_2\sqrt{1-\rho^2})^l \exp\Big[-\frac{1}{2(1-\rho^2)}\Big\{\frac{(x_1-\mu_1)^2}{\sigma_1^2} - 2\rho\,\frac{(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1\sigma_2} + \frac{(x_2-\mu_2)^2}{\sigma_2^2}\Big\}\,\Big] \end{split}$$

(ii) Multivariate normal (with mean vector $\boldsymbol{\mu}$ and variance-covariance matrix $\boldsymbol{\Sigma}$) $N_{\rho}(\mathbf{x} \mid \boldsymbol{\mu}, \boldsymbol{\Sigma}) = (2\pi)^{-1/2} |\boldsymbol{\Sigma}|^{-1/2} \exp \left[-\frac{1}{2} (\mathbf{x} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu})\right]$

where Σ^{-1} is the inverse of Σ .

(iii) Wishart distribution

$$W_p(\mathbf{S} \mid \mathbf{v}, \mathbf{\Sigma}) = \left[2^{p/2} \pi^{p(p-1)/4} \prod_{i=1}^p \Gamma\left(\frac{\mathbf{v} - i + 1}{2}\right) \right]^{-1} \times \left| \mathbf{\Sigma} \right|^{-1/2} \left| \mathbf{S} \right|^{(\nu-p-1)/2} e^{-(\operatorname{tr} \mathbf{\Sigma}^{-1} \mathbf{S})/2}$$

If $X_1, X_2 ..., X_\nu$ are independent $N_p(0, \Sigma)$ variables then $S = \sum_{i=1}^{\nu} X_i X_i$ has the above distribution.

(iv) Noncentral χ^2

$$\chi^{2}(x \mid \nu, \lambda) = e^{-\frac{\lambda}{2} \sum_{r=0}^{\infty} \frac{1}{r!} \left(\frac{\lambda}{2}\right)^{r} G\left(x \mid \frac{1}{2}, \frac{\nu}{2} + r\right), \ 0 < x < \infty$$

where ν is called degrees of freedom, λ the noncentrality parameter, and

$$G(x \mid \alpha, p) = \alpha^{p} [\Gamma(p)]^{-1} e^{-x\alpha} x^{p-1}.$$

Note: The distribution of $\sum x_i^2$, where x_i is distributed as $N_1(\mu_i, \sigma^2)$ and x_i are all independent, is non-central $\chi^2(\nu, (\sum \mu_i^2)/\sigma^2)$.

(v) Noncentral t

$$t(x \mid \nu, \delta) = \frac{\nu^{\nu/2}}{\Gamma\left(\frac{\nu}{2}\right)} \frac{e^{-\delta^2/2}}{(\nu + x^2)^{(\nu+1)/2}} \sum_{r=0}^{\infty} \Gamma\left(\frac{\nu + r + 1}{2}\right) \left(\frac{\delta^r}{r!}\right) \left(\frac{2x^2}{\nu + x^2}\right)^{r/2}$$

with $-\infty < x < \infty$, where v is the degrees of freedom and δ is the noncentrality parameter.

Note: The distribution of $X/\sqrt{(Y/\nu)}$ where X and K are independently distributed, X as $N(\delta, 1)$ and Y as $\chi^2(\nu)$ variates, is noncentral $t(\nu, \delta)$.

(vi) Noncentral F

$$F(x \mid \mathbf{v_1}, \mathbf{v_2}, \lambda) = e^{-\lambda^2/2} \frac{\left(\frac{\mathbf{v_1}}{\mathbf{v_2}}\right)^{\frac{\mathbf{v_1}}{2}} \mathbf{v_2} - 1}{B\left(\frac{\mathbf{v_1}}{2}, \frac{\mathbf{v_2}}{2}\right) \left(1 + \frac{\mathbf{v_1}}{\mathbf{v_2}}x\right)^{\frac{\mathbf{v_1} + \mathbf{v_2}}{2}} \mathbf{1} F_1\left(\frac{\mathbf{v_1} + \mathbf{v_2}}{2}, \frac{\mathbf{v_1}}{2}, \frac{\lambda^2 \mathbf{v_1} x}{2(\mathbf{v_2} + \mathbf{v_1} x)}\right)$$

with $0 \leqslant x < \infty$, where ${}_{1}F_{1}$ is the hypergeometric function of the first kind defined by

$$_1F_1(a, b, y) = \sum_{r=0}^{\infty} \frac{\Gamma(a+r)}{\Gamma(a)} \frac{\Gamma(b)}{\Gamma(b+r)} \frac{y^r}{r!}.$$

Note: The distribution of $(X/\nu_1)/(Y/\nu_2)$, where X and Y are independently distributed, X being non-central $\chi^2(\nu_1, \lambda)$ and Y a central $\chi^2(\nu_2)$, is noncentral $F(\nu_1, \nu_2, \lambda)$.

(vii) Multiple correlation

Let R^2 be the square of the multiple correlation, based on a sample of size n, of one variable on p-1 other variables. If the latter are considered fixed, then the density function of R^2 is

$$R^{2}(x \mid p, n, \delta) = e^{-\delta^{2}/2} B\left(x \mid \frac{p-1}{2}, \frac{n-p}{2}\right) {}_{1}F_{1}\left(\frac{n-1}{2}, \frac{p-1}{2}, \frac{\delta^{2}R^{2}}{2}\right)$$

with $0 \le x < \infty$, which is called multiple correlation distribution of the first kind. If variations in the (p-1) variables are allowed, then the density function is

$$R^2(\mathbf{x} \mid p, n, \rho) = (1 - \rho^2)^{(n-1)/2} B\left(x \mid \frac{p-1}{2}, \frac{n-p}{2}\right)_2 F_1\left(\frac{n-1}{2}, \frac{n-1}{2}, \frac{p-1}{2}, \rho^2 x\right)$$

with $0 \le x \le 1$, where ρ is the population multiple correlation coefficient and ${}_2F_1$ is the hypergeometric function of the second kind defined by

$$_{2}F_{1}(a, b, c, y) = \sum_{r=0}^{\infty} \frac{\Gamma(a+r)}{\Gamma(a)} \frac{\Gamma(b+r)}{\Gamma(b)} \frac{\Gamma(c)}{\Gamma(c+r)} \frac{y^{r}}{r!},$$

and
$$B(x | a, b) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} x^{a-1} (1-x)^{b-1}$$

(viii) Hotelling's T2, Mahalanobis' D2

$$T^2(x \mid p, v, c \tau^2) = \frac{v-p+1}{p} F\left(\frac{v-p+1}{p} x \mid p, v-p+1, c\tau^2\right)$$

where the function F is that of non-central F distribution.

Note: The distribution of \mathbf{d}' \mathbf{S}^{-1} \mathbf{d} has the above form if \mathbf{d} has the p-variate normal distribution $N_p(\mathbf{\delta}, \mathbf{c}^{-1} \mathbf{\Sigma})$, c a scalar, and the elements of the matrix \mathbf{S} have an independent Wishart distribution $W_p(\mathbf{S}, \mathbf{\Sigma})$. In such a case $\tau^2 = \mathbf{\delta} \mathbf{\Sigma}^{-1} \mathbf{\delta}'$.

IV STANDARD ERRORS

a. Application

In large sample theory, hypotheses concerning unknown population parameters, can be tested in a simple way by using efficient estimators and their standard errors.

Thus if T is an estimator of θ based on n observations and $\sigma(\theta)/\sqrt{n}$ is the standard error of T, then to test the hypothesis $H_0: \theta = \theta^0$, $\sqrt{n}(T-\theta^0)/\sigma(\theta^0)$ will be used as a standard normal deviate.

To test whether two parallel independent estimators T_1 and T_2 with standard errors $\sigma_1(\theta)/\sqrt{n_1}$ and $\sigma_2(\theta)/\sqrt{n_2}$ are in agreement (i.e., whether they estimate the same parametric value) the appropriate standard normal deviate will be

$$(T_1 - T_2) \div \sqrt{\frac{\sigma_1^2(T_1)}{n_1} + \frac{\sigma_2^2(T_2)}{n_2}}$$

where in the expressions for standard errors, estimates are substituted for unknown parameters provided $\sigma_1(\theta)$ and $\sigma_2(\theta)$ are continuous functions of θ .

To test whether k parallel independent estimators $T_1, T_2, ..., T_k$ having standard errors $\sigma_1(\theta)/\sqrt{n_1}$, $\sigma_2(\theta)/\sqrt{n_2}$, ..., $\sigma_k(\theta)/\sqrt{n_k}$, are in agreement, the test-statistic

$$H = \sum_{i=1}^{k} \frac{n_i}{\sigma_i^2(T_i)} (T_i - \overline{T})^2$$

may be used as a chi-square with k-1 d.f., where

$$\overline{T} = \sum_{i=1}^{k} \frac{n_i T_i}{\sigma_i^2(T_i)} / \sum_{i=1}^{k} \frac{n_i}{\sigma_i^2(T_i)}$$

b. Standard errors of some statistics

Notations for population parameters:

 $\mu_1 = \text{mean}, \qquad \mu_r = r\text{-th central moment}$

 $\beta_{2n} = \mu_{2n+2}/\mu_2^{n+1}, \quad \beta_{2n+1} = \mu_3\mu_{2n+3}/\mu_2^{n+3}$

 $\mu_{rs} = (r, s)$ -th bivariate central moment

 $ho = ext{correlation coefficient}$

 $\theta = \text{percentage coefficient of variation}$

 $\delta =$ mean deviation about the mean

 Δ = Gini's mean difference

 $\phi = E |X-Y| |X-Z|$ where X, Y, Z are three independent observations drawn from the same population

= ordinate at the p-th quantile.

The standard errors of some of the more common statistics are given below STANDARD ERRORS OF SOME STATISTICS

(To obtain the standard error, divide the tabular entry by n, the sample size and take the square root)

statistic	arbitrary distribution	normal distribution
mean x	$\mu_2 (=\sigma^2)$	σ^2
variance s ²	$\mu_4 - \mu_2^2$	$2\sigma^4$.
standard deviation s	$(\mu_4 - \mu_2^2)/4\mu_2$	$\sigma^2/2$
k -th central moment m_k	$\mu_{2k} - \mu_k^2 + k^2 \mu_2 \mu_{k-1}^2 - 2k \mu_{k-1} \mu_{k+1}$	
coefficient of variation (%)	$\theta^{2} \left[\frac{\mu_{4} - \mu_{3}^{2}}{4\mu_{3}^{2}} + \frac{\mu_{2}}{\mu_{1}^{'2}} - \frac{\mu_{3}}{\mu_{2}\mu_{1}^{'}} \right]$	$-\frac{\theta^2}{2}\left[1+2\left(\frac{\theta}{100}\right)^2\right]$
sample $\sqrt{\beta_1}$	$[4\beta_4 - 24\beta_2 + 36 + 9\beta_1\beta_2 - 12\beta_3 + 35\beta_1]/4$	6
sample β_2	$\beta_6 - 4\beta_2\beta_4 + 4\beta_2^2 - \beta_2^2 + 16\beta_2\beta_1 - 8\beta_3 + 16\beta_1$	24
mean deviation about sample mean	$\sigma^2 - \delta^2$	$\sigma^2(1-2/\pi)$
Gini's mean difference	$4(\phi-\Delta^2)$	(0.8068)2σ2
median x	1/490.5	$(1.2533)^2\sigma^2$
quartile _.	$3/4y^2(y=y_{0\cdot 25} \text{ or } y_{0\cdot 75})$	$(1.3626)^2\sigma^2$
p-th quantile*	$p(1-p)/y_p^2$	
semi-interquartile range	$\frac{1}{4} \left[\begin{array}{c} \frac{3}{16} \left(y_{0.25}^{-2} + y_{0.75}^{-2} \right) - \frac{1}{8} y_{0.25}^{-1} y_{0.75}^{-1} \right]$	(0.7867) ² σ ²
correlation coefficient	$ \rho^{2} \left[\frac{\mu_{22}}{\mu_{11}^{2}} + \frac{1}{4} \left(\frac{\mu_{40}}{\mu_{10}^{2}} + \frac{\mu_{04}}{\mu_{02}^{2}} + \frac{2\mu_{22}}{\mu_{20}\mu_{02}} \right) \right] $	(1-p ²) ²
	$-\left(\frac{\mu_{31}}{\mu_{11}\mu_{20}}+\frac{\mu_{13}}{\mu_{11}\mu_{02}}\right)\right]$	

* for a normal population the standard errors of the sample deciles are as follows:

4th and 6th deciles: $1.2680\sigma/\sqrt{n}$, 3rd and 7th deciles: $1.3180\sigma/\sqrt{n}$ 2nd and 8th deciles: $1.4288\sigma/\sqrt{n}$, 1st and 9th deciles: $1.7094\sigma/\sqrt{n}$.

The asymptotic covariance between the p-th and p'-th quantiles (p < p') is pq'/ny_py_p , where q' = 1-p'. Thus for a normal distribution the asymptotic covariance between the first quartile and the median is equal to $0.9860\sigma^2/n$.

c. Transformation of statistics

For the application of techniques such as the analysis of variance it may be necessary to use transformed value of an estimate so that the asymptotic variance (square of the standard error) is independent of the unknown parameter. Some standard transformations and the corresponding asymptotic variances appear in the table given in the next page

d. Normalisation of frequency functions

A large number of statistics tend to be normally distributed as sample size n increases. Let T be such a statistic with k_i as its i-th cumulant. Assume further the existence of constants μ and σ such that

$$\begin{split} & \rho_1 = (k_1 - \mu)/\sigma = O(n^{-\frac{1}{2}}) \\ & \rho_2 = (k_2 - \sigma^2)/\sigma^2 = O(n^{-1}) \\ & \rho_r = k_r/\sigma^r = O(n^{1-\frac{1}{2}r}) \qquad \text{for} \quad r = 3, 4, \ldots, . \end{split}$$

and

Define $x = (T - \mu)/\sigma$. The following equation, gives to order n^{-2} , an expression for a transformed variable y which has standard normal distribution:

$$x-y = \rho_1 + \frac{1}{6} \rho_3(x^2-1) + \frac{1}{2} \rho_2 x - \frac{1}{3} \rho_1 \rho_3 x + \frac{1}{24} \rho_4(x^3-3x)$$

$$-\frac{1}{36} \rho_3^2(4x^3-7x) - \frac{1}{2} \rho_1 \rho_2 + \frac{1}{6} \rho_1^2 \rho_3 - \frac{1}{12} \rho_2 \rho_3(5x^2-3) - \frac{1}{8} \rho_1 \rho_4(x^2-1)$$

$$+\frac{1}{120} \rho_5(x^4-6x^2+3) + \frac{1}{36} \rho_1 \rho_3^2(12x^2-7) - \frac{1}{144} \rho_3 \rho_4(11x^4-42x^2+15)$$

$$+\frac{1}{648} \rho_3^3(69x^4-187x^2+52) - \frac{3}{8} \rho_2^2 x + \frac{5}{6} \rho_1 \rho_2 \rho_3 x + \frac{1}{8} \rho_1^2 \rho_4 x - \frac{1}{48} \rho_2 \rho_4(7x^3-15x)$$

$$-\frac{1}{30} \rho_1 \rho_5(x^3-3x) + \frac{1}{720} \rho_6(x^5-10x^3+15x) - \frac{1}{3} \rho_1^2 \rho_3^2 x + \frac{1}{72} \rho_2 \rho_3^2(36x^3-49x)$$

$$-\frac{1}{384} \rho_4^2(5x^5-32x^3+35x) + \frac{1}{36} \rho_1 \rho_3 \rho_4(11x^3-21x) - \frac{1}{360} \rho_3 \rho_5(7x^5-48x^3+51x)$$

$$-\frac{1}{324} \rho_1 \rho_3^3(138x^3-187x) + \frac{1}{864} \rho_3^2 \rho_4(111x^5-547x^3+456x)$$

$$-\frac{1}{7776} \rho_3^4(948x^5-3628x^3+2473x).$$

The following equation connecting x with y is equally useful:

$$\begin{split} x-y &= \rho_1 + \frac{1}{6} \, \rho_3(y^2-1) + \frac{1}{2} \, \rho_2 y + \frac{1}{24} \, \rho_4(y^3-3y) - \frac{1}{36} \, \rho_3^2(2y^3-5y) \, - \frac{1}{6} \, \rho_2 \rho_3(y^2-1) \\ &+ \frac{1}{120} \, \rho_5(y^4-6y^2+3) - \frac{1}{24} \, \rho_3 \rho_4(y^4-5y^2+2) + \frac{1}{324} \, \rho_3^3(12y^4-53y^2+17) \\ &- \frac{1}{8} \, \rho_2^2 y - \frac{1}{16} \, \rho_2 \rho_4(y^3-3y) + \frac{1}{720} \, \rho_5(y^5-10y^3+15y) + \frac{1}{72} \, \rho_2 \rho_3^2(10y^3-25y) \\ &- \frac{1}{384} \, \rho_4^2(3y^5-24y^3+29y) - \frac{1}{180} \, \rho_3 \rho_5(2y^5-17y^3+21y) \\ &+ \frac{1}{288} \, \rho_3^2 \rho_4(14y^5-103y^3+107y) - \frac{1}{7776} \, \rho_3^4(252y^5-1688y^3+1511y). \end{split}$$

Special cases of this formula corresponding to the t, χ^2 and F distributions are discussed in appropriate sections dealing with the different tables relating to these statistics.

V. SAMPLE SURVEY ESTIMATES AND THEIR STANDARD ERRORS

a. Notations

The following notations^(1, 2) are used for sample statistics and the corresponding population characteristics where y indicates the primary variate under investigation, x a supplementary variate and r the variable ratio y/x.

	sample	population
number of units	n	N
sampling fraction	$f = \frac{n}{N}$	
raising factor	$g = \frac{1}{f}$. —
summation over constituent units	S	Σ
arithmetic mean of y, x, r	$ar{y}, x, ar{r}$	μ_y, μ_x, μ_t
ratio of means	$\hat{\xi} = \frac{\bar{y}}{\bar{x}}$	$\xi = rac{\mu_y}{\mu_x}$
variance of $y^{(3)}$	$s_y^2 = \int_{n-1}^{1} S(y - \bar{y})^2$	$\sigma_y^2 = rac{1}{N} \Sigma (y - \mu_y)^2$
		$\sigma_y^{'2} = \frac{1}{N-1} \Sigma (y - \mu_y)^2$
covariance of x and y	$s_{xy} = \frac{1}{n-1} S(x-\bar{x})(y-\bar{y})$	$\sigma_{xy} = \frac{1}{N} \Sigma(x - \mu_x)(y - \mu_y)$
		$\sigma'_{xy} = \frac{1}{N-1} \sum_{x} (x - \mu_x)(y - \mu_y)$
regression coefficient $(y \text{ on } x)$	$b = \frac{s_{xy}}{s_x^2}$	$eta = rac{\sigma_{xy}}{\sigma_x^2}$

⁽¹⁾ A suffix i to these symbols will imply that the corresponding definition has to be understood in terms of the i-th stratum.

⁽²⁾ A curl on top will represent sample estimate. Thus $\hat{\mu}_y$ represents the estimate of μ_y and $\hat{V}(\hat{\mu}_y)$ represents an estimate of $V(\hat{\mu}_y)$ the variance of $\hat{\mu}_y$.

⁽³⁾ Sample (population) variance of x, r denoted by s_x^2 , $(\sigma_x^2, \sigma_x^{\prime 2})$ and s_r^2 , $(\sigma_r^2, \sigma_r^{\prime 2})$ are define in a similar manner.

b. Common methods of sampling, estimates, and standard errors

method of sampling	estimate	formula for variance of estimate ^(1,2)
simple random sampling	$ar{y}$	$\frac{1-f}{n} \sigma_y^{\prime 2}$
Stratified simple random ⁽³⁾ sampling	$\Sigma \pi_i ilde{y}_i \ (\pi_i = N_i / N)$	$\Sigma \pi_i^2 \; rac{(1-f_i)}{n_i} \; \sigma_{yi}^{'2}$

- (1) The formula is given for 'without replacement' sampling. For sampling with replacement the formula is obtained by putting the corresponding f = 0 and properly the prime (') from the corresponding σ'^2 .
- (2) The expression for an estimate of this variance is obtained by substituting s_y^2 for $\sigma_y'^2$ (or σ_y^2) and s_{yi}^2 for $\sigma_{yi}'^2$ (or σ_{yi}^2) wherever necessary.
 - (3) For stratified sampling, in the general case, the formulae for estimate and its variance are

$$\hat{\mu}_y = \sum \pi_i \hat{\mu}_{yi}, \ V(\hat{\mu}_y) = \sum \pi_i^2 V(\hat{\mu}_{yi})$$

where $\hat{\mu}_{yi}$ is the estimate for i-th stratum mean and $V(\hat{\mu}_{yi})$ is the variance of the estimate

c. Methods of estimation using supplementary variable

For simple random sampling, when μ_x is known, the formulae are as follows:

method of estimation,	estimate	formula ^(1, 2) for variance of estimate ⁽³⁾
ratio method	$rac{ar{y}}{ar{x}}\;\mu_x$	$\frac{1-f}{n} (\sigma_y^{'2} - 2\xi \sigma_{xy}^{'} + \xi^2 \sigma_x^{'2})$
product method	$ar{y}ar{x}$	$\frac{1-f}{n} \ (\sigma_y^{'2} + 2\xi \sigma_{xy}^{'} + \xi^2 \sigma_x^{'2})$
difference method	$(\bar{y}-\bar{x})+\mu_x$	$\frac{1-f}{t}\left(\sigma_{y}^{\prime2}-2\sigma_{xy}+\sigma_{x}^{\prime2}\right)$
regression method ⁽⁴⁾	$\hat{y} + b(\mu_x - \bar{x})$	$\frac{1-f}{n} (\sigma_y^{'2} - \beta^2 \sigma_x^{'2})$

⁽¹⁾ The formula for variance is approximate except for the difference method. The approximation assumes that the sample size is large.

⁽²⁾ The formula is given for 'without replacement' sampling. For sampling with replacement the formula is obtained by putting f=0 and by dropping the prime (') in σ_x , σ_y and σ_{xy} .

⁽³⁾ The expression for an estimate of the variance is obtained by substituting s_x^2 for $\sigma_x'^2$ (or σ_x^2), s_y^2 for $\sigma_y'^2$ (or $\sigma_y'^2$), s_{xy} for σ_{xy} (or σ_{xy}), $\hat{\xi}$ for ξ and b for β wherever necessary.

The regression coefficient b is estimated from the sample on (y, x) by the formula s_{xy}/s_x^2 (see the table of notations).

d. Modifications required for two-phase sampling

Consider the situation when μ_x is unknown and sampling for x is cheaper than sampling for y. In such cases, we take a sample of size n units for obtaining x and y and an independent and larger sample (of size n' and sampling fraction f' > f) covering the x's only. Then an estimate of μ_x is obtained from the second sample and substituted in the formula for estimates in section c. For such estimates of μ_y , expressions for variance would be as follows.

method of estimation	formula ^(1, 2) for variance of estimate ⁽³⁾ in two-phase sampling
ratio method	$\frac{1-f}{n} (\sigma_y^{'2} - 2\xi\sigma_{xy}^{'} + \xi^2\sigma_x^{'2}) + \frac{1-f'}{n'} \xi^2\sigma_x^{'2}$
product method	$\frac{1-f}{n}(\sigma_y^{'2}+2\xi\sigma_{xy}^{'}+\xi^2\sigma_x^{'2})+\frac{1-f^{'}}{n^{'}}\xi^2\sigma_x^{'2}$
difference method	$\frac{1-f}{n} \left(\sigma_y^{'2} - 2\sigma_{xy}^{'} + \sigma_x^{'2} \right) + \frac{1-f^{'}}{n^{'}} \sigma_x^{'2}$
regression method	$rac{1-f}{n} \left(\sigma_{y}^{'2} - eta^{2} \sigma_{x}^{'2} ight) + rac{1-f'}{n'} eta^{2} \sigma_{x}^{'2}$

^{(1), (2)} and (3). See footnote to table in section c.

e. Sampling with replacement and with probabilities proportional to size (x)

Estimate: $\hat{\mu}_y = \bar{r}\mu_x$

Variance of estimate: $V(\hat{\mu}_y) = \frac{\mu_z^2 \sigma_x^2}{n}$

Estimate of variance : $\hat{V}(\hat{\mu}_y) = \frac{\mu_x^2 s_r^2}{n}$

f. Two-stage sampling schemes

A two-stage sampling scheme specifies m_1 , the number of first stage units that will be selected in the sample out of a total of M_1 such units in the population and also m_{2i} , the number of second stage units (subunits) that will be included in the sample out of a total of M_{2i} subunits contained in the *i*-th first stage unit in case

this particular first stage unit is chosen through the first stage selection. Let

$$g_1 = \frac{1}{f_1} = \frac{M_1}{m_1}$$

$$g_{2i} = \frac{1}{f_{2i}} = \frac{M_{2i}}{m_{2i}}.$$

Note that though g_1 is necessarily a constant g_{2i} could possibly vary from one first stage unit to another. For the *i*-th first stage unit let the total, mean and variance of all the second stage units be denoted by τ_{yi} , μ_{yi} and σ_{vi}^2 and if the *i*-th first stage unit is included in the sample, let the corresponding sample figures be denoted by T_{yi} , \bar{y}_i and s_{yi}^2 . If the first stage selection is based on simple random sampling, we have

Estimate:

$$\hat{\mu}_y = rac{g_1 S \hat{ au}_{yi}}{N}$$

and

Variance:

$$V(\hat{\mu}_y) = \frac{1 - f_1}{m_1} (\sigma_1')^2 + \frac{g_1}{N^2} \sum_i V(\hat{\tau}_{yi})$$

where $N = \sum M_{2i}$, $(\sigma_1')^2 = \frac{M_1^2}{N^2} \left\{ \frac{1}{M_1 - 1} \sum (\tau_{yi} - \bar{\tau}_y)^2 \right\}$, $\bar{\tau}_y = \frac{1}{M_1} \sum \bar{\tau}_{yi} = \frac{N}{M_1} \mu_y$. For example for a simple random sample of second stage unit $g_{2i} T_{yi}$ provides an unbiased estimate for τ_{yi} and $V(g_{2i} T_{yi}) = \frac{M_{2i}^2 (1 - f_2)}{m_{2i}} (\sigma_{yi}')^2$. In the special case where $M_{2i} = M_2$ and $m_{2i} = \dot{m}_2$ $(i = 1, 2, ..., M_1)$ this estimate of τ_{yi} leads to the following estimate of μ_y

$$\hat{\mu}_y = ar{ar{y}} = rac{1}{m_1} \, {}_i^S ar{y}_i$$

the grandmean of all the sample observations. We have

$$V(\bar{\bar{y}}) = \frac{1 - f_1}{m_1} (\sigma_1')^2 + \frac{1 - f_2}{m_1 m_2} (\sigma_2')^2$$

where

$$(\sigma_1')^2 = \frac{1}{M_1 - 1} \; \Sigma (\mu_{yi} - \mu_y)^2 \; \text{and} \; (\sigma_2')^2 = \frac{1}{M_1} \; \frac{\Sigma}{i} \; (\sigma_{yi}')^2,$$

and

$$\hat{V}(\bar{\bar{y}}) = \frac{1 - f_1}{m_1} \, s_1^2 + f_1 \, \frac{1 - f_2}{m_1 m_2} \, s_2^2$$

where

$$s_1^2 = \frac{1}{m_1 - 1} \sum_i (\bar{y}_i - \bar{\bar{y}})^2$$
 and $s_2^2 = \frac{1}{m_1} \sum_i s_{yi}^2$.

VI. NUMERICAL ANALYSIS

a. Interpolation

Interpolation is a process for determining approximately the value of a function y = f(x) at an untabulated value x of the argument within the range of tabulation, on the basis of a given set of tabulated values of the function. In polynomial interpolation the knowledge of the tabulated values is used to estimate the function, the form of which may be unknown, by a polynomial of sufficiently high degree and the approximating polynomial is used to compute the required intermediate value. Some formulae for polynomial interpolation are given in this chapter. These are appropriate for tables in which values of the argument are given at equidistant intervals.

The formulae involve first and higher order differences which are calculated as shown below. Note that

$$\Delta y_i = y_{i+1} - y_i$$
, $\Delta^2 y_i = \Delta y_{i+1} - \Delta y_i$ etc....

TABLE OF DIFFERENCES

æ	y_x Differences						
:	:						
x_3	y_3						
		Δy_{-3}					
x_2	y_2		$\Delta^2 y_{-3}$				
		Δy_{-2}		$\Delta^3 y_{-3}$	•		
x_{-1}	¥-1		$\Delta^2 y_{-2}$		$\Delta^4 y_{-3}$,
		$\Delta y_{\scriptscriptstyle -1}$		$\Delta^3 y_{-2}$		$\Delta^5 y_{-3}$	
æ ₀	\underline{y}_0		$\underline{\Delta^2 y_{-1}}$		$\Delta^4 y_{-2}$		$\Delta^6 y_{-3}$
1		Δy_0		$\Delta^3 y_{-1}$		$\Delta^5 y_{-2}$	
x_1	y_1		$\Delta^2 y_0$		$\Delta^4 y_{-1}$		
		Δy_1		$\Delta^3 y_0$			
x2	<i>y</i> ₂		$\Delta^2 y_1$				
		Δy_2					
x_3	<i>y</i> ₃	٠					
:	:						

Note: Differences underlined or in bold face have special significance only with respect to the explanation of certain formulae appearing in the next section. Those underlined appear in Bessel's formula and those in bold face in Stirling's formula,

b. Formulae

Let x be the value of the argument at which it is desired to interpolate and h the interval of the argument at which the ordinates are tabulated. Write $u=(x-x_0)/h$ where x_0 is a chosen value of the argument called the initial argument. Four main formulae are given depending on the nature of the subsequent arguments chosen in relation to initial argument x_0 .

Newton's Forward Formula using arguments x_0, x_1, x_2, \ldots

$$y = y_0 + u\Delta y_0 + \frac{u(u-1)}{2!} \Delta^2 y_0 + \ldots + \frac{u(u-1) \ldots (u-m+1)}{m!} \Delta^m y_0 + \ldots$$

Note that the first (m+1) terms give a polynomial of the m-th degree fitted to y_0, y_1, \ldots, y_m . The differences used are chosen from the principal diagonal (downwards) of the difference table starting from the initial ordinate y_0 . The addition of the ordinate y_{m+1} brings in the correction term

$$\frac{u(u-1)\dots(u-\overline{m+1}+1)}{(m+1)!} \Delta^{m+1}y_0$$

which involves the (m+1)th order difference at y_0 .

Newton's Backward Formula using arguments $x_0, x_{-1}, x_{-2}, \dots$

$$y = y_0 + u\Delta y_{-1} + \frac{u(u+1)}{2!} \Delta^2 y_{-2} + \dots + \frac{u(u+1) \dots (u+m-1)}{m!} \Delta^m y_{-m} + \dots$$

Note that the first (m+1) terms give a polynomial of the m-th degree fitted to $y_0, y_{-1}, ..., y_{-m}$. The differences used are chosen from the principal diagonal (upwards) of the difference table starting from the initial ordinate y_0 . The addition of the ordinate y_{-m-1} brings in the correction term

$$\frac{u(u+1)\dots(u+m+1-1)}{(m+1)!} \Delta^{m+1} y_{-m-1}.$$

Stirling's Formula (for -1/4 < u < 1/4, using arguments) $x_0, x_{-1}, x_1, x_{-2}, x_2, \dots$

$$\begin{split} y &= y_0 + u \frac{\Delta y_{-1} + \Delta y_0}{2} + \frac{u^2}{2!} \Delta^2 y_{-1} + \frac{u[u^2 - 1^2]}{3!} \frac{\Delta^3 y_{-2} + \Delta^3 y_{-1}}{2} + \frac{u^2[u^2 - 1^2]}{4!} \Delta^4 y_{-1} + \\ & \dots + \frac{u[u^2 - 1^2] \dots [u^2 - (m-1)^2]}{(2m-1)!} \frac{\Delta^{2m-1} \hat{y}_{-m} + \Delta^{2m-1} y_{-m+1}}{2} \\ & + \frac{u^2[u^2 - 1^2) \dots [u^2 - (m-1)^2]}{2m!} \Delta^{2m} \ y_{-m} + \dots \end{split}$$

Note that the first 2m+1 terms give the polynomial of degree 2m fitted to y_0 , $y_{-1}, y_{+1}, y_{-2}, y_{+2}, \dots, y_{-m}, y_{+m}$. The differences used are chosen as indicated (in bold face) in the table of differences. The addition of ordinates y_{-m-1} and y_{m+1} brings in the correction terms:

$$\frac{u[u^2-1^2]\dots[u^2-m^2]}{(2m+1)!} \frac{\Delta^{2m+1}y_{-m-1}+\Delta^{2m+1}y_{-m}}{2} + \frac{u^2[u^2-1^2]\dots[u^2-m^2]}{(2m+2)!} \Delta^{2m+2}y_{-m-1}.$$

Bessel's Formula (for -1/4 < v < 1/4, $v = u - \frac{1}{2}$) using arguments $x_0, x_1, x_{-1}, x_2, \dots$

$$\begin{split} y &= \frac{y_0 + y_1}{2} + v \Delta y_0 + \frac{\left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{2!} \right] - \Delta^2 y_{-1} + \Delta^2 y_0}{2!} + \frac{v \left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{3!} \right] - \Delta^3 y_{-1} + \\ &+ \frac{\left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{2} \right] \left[\frac{v^2 - \left(\frac{3}{2}\right)^2}{2} \right] - \Delta^4 y_{-2} + \Delta^4 y_{-1}}{2} + \frac{v \left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{2} \right] \left[\frac{v^2 - \left(\frac{3}{2}\right)^2}{2} \right] - \Delta^5 y_{-2} + \dots}{4!} \\ &+ \frac{\left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{2} \right] \left[\frac{v^2 - \left(\frac{3}{2}\right)^2}{2} \right] - \left[\frac{v^2 - \left(\frac{2m - 3}{2}\right)^2}{2} \right] - \Delta^{2m - 2} y_{-m + 1} + \Delta^{2m - 2} y_{-m + 2}}{2} \\ &+ \frac{v \left[\frac{v^2 - \left(\frac{1}{2}\right)^2}{2} \right] \left[\frac{v^2 - \left(\frac{3}{2}\right)^2}{2} \right] - \left[\frac{v^2 - \left(\frac{2m - 3}{2}\right)^2}{2} \right] - \Delta^{2m - 1} y_{-m + 1} + \dots}{2} \end{split}$$

Note that the first 2m terms give the polynomial of degree 2m-1 fitted to $y_0, y_1, y_{-1}, y_2, \dots, y_{-m+1}, y_m$. The differences used are chosen as indicated (underlined) in the table of differences. The addition of ordinates y_{-m}, y_{m+1} , brings in the correction terms

$$\frac{\left[v^{2} - \left(\frac{1}{2}\right)^{2} \right] \left[v^{2} - \left(\frac{3}{2}\right)^{2} \right] \dots \left[v^{2} - \left(\frac{2m-1}{2}\right)^{2} \right]}{2m!} \Delta^{2m} y_{-m} + \Delta^{2m} y_{-m+1}}$$

$$+ v \left[v^{2} - \left(\frac{1}{2}\right)^{2} \right] \left[v^{2} - \left(\frac{3}{2}\right)^{2} \right] \dots \left[v^{2} - \left(\frac{2m-1}{2}\right)^{2} \right]}{(2m+1)!} \Delta^{2m+1} y_{-m}.$$

c. Choice of formulae

Once the tabulated values to be used for interpolation are selected, it is immaterial which formula is used to obtain the desired value. For example if f(7), f(9), f(11), f(13), f(15) are available and it is decided that all these values should be used for obtaining f(11.4) one may stop with the fifth term of either Newton's Forward formula (with $x_0 = 7$ and $u = (11.4-7) \div 2 = 2.20$) or Stirling's formula (with $x_0 = 11$, $u = (11.4-11) \div 2 = 0.20$) the result obtained being the same, as the m-th degree polynomial whose values coincide with the values of the function at the (m+1) selected arguments is unique. But in practice, after obtaining an interpolated

value based on a certain number of arguments, one may decide to consider a few more and compute the necessary correction to the value already obtained. The different formulae listed above are useful in different situations, depending on the positions of the additional arguments in relation to those already used. Newton's formulae requires the knowledge of additional tabulated values for arguments that are always on one side of x_0 , moving further away from x_0 at each successive step. With Stirling's and Bessel's formulae the extra terms utilised will be chosen symmetrically from either side of x_0 .

To begin with, the tabulated value of the argument close to x is chosen as x_0 giving the first approximation to y as y_0 . If the subsequent values chosen are x_1, x_2, \ldots , Newton's Forward formula is used for step-by-step correction. If the subsequent values chosen are x_{-1}, x_{-2}, \ldots , Newton's Backward formula is used. If the subsequent values chosen are in pairs $(x_{-1}, x_1), (x_{-2}, x_2), \ldots$ Stirling's formula is chosen. Or, one may begin with the pair (x_0, x_1) giving the first approximation to y as $(y_0+y_1)/2+(u-\frac{1}{2})\Delta y_0$, and then add the pair (x_{-1}, x_2) and so on. In such a case, Bessel's formula is used. Note that in each case, we add extra terms to the formula already obtained, as we bring in additional arguments either individually or in pairs.

d. Switching from one formula to another

It is not necessary to choose the arguments in only one particular manner throughout, in any given problem. If the tabular entries are limited on one side, it is not possible to carry out the central difference formula (Bessel or Stirling) to any sufficient length. Then the procedure is to use the central difference formula so long as the tabular entries permit, and then switch over to Newton's Forward or Backward formula, depending upon the direction in which subsequent values are chosen. The switching over is done only to obtain the correction terms by the new formulae without altering the approximation already obtained by the earlier formula. Thus, suppose in the numerical example considered above the fourth degree polynomial approximation obtained through Stirling's formula is found inadequate and further tabulated values are available only on one side of 11.4, say f(17), f(19), ..., then corrections to the interpolated value could be obtained from the sixth and succeeding terms of Newton's Forward formula.

$$\frac{u(u-1)\dots(u-5)}{6!} \Delta^{6}f(7) + \frac{u(u-1)\dots(u-6)}{7!} \Delta^{7}f(7) + \dots$$

where u = (x-7)/2 = 2.2.

Some quadrature formulae

Numerical differentiation and integration are processes for approximate evaluation of derivatives and of definite integrals respectively when the function concerned is defined only by a table of ordinate values at discrete points. In either process, the function is first replaced by an interpolation polynomial which is conveniently differentiated or integrated. The numerical integration coefficients in Table 15.1 were obtained on the basis of Stirling's formula.

Simple quadrature formulae using the ordinates within the range of integration are given below.

(i) Simpson's one third rule (3 ordinates)

$$\int_{a}^{b} f(x)dx = \frac{b-a}{6} \left\{ f(a) + 4f\left(\frac{a+b}{2}\right) + f(b) \right\}.$$

(ii) Extension of Simpson's rule by repeated application (2n+1 ordinates)

$$\int_{a}^{b} f(x)dx = \frac{h}{3} \left\{ f(a) + 4f(a+h) + 2f(a+2h) + 4f(a+3h) + \dots + f(b) \right\}$$

where h = (b-a)/2n and n is an integer to be chosen.

(iii) Three eighths rule (4 ordinates)

$$\int_{a}^{b} f(x)dx = \frac{b-\alpha}{16} \left\{ 2[f(a)+f(b)] + 6\left[f\left(\frac{2a+b}{3}\right) + f\left(\frac{a+2b}{3}\right)\right] \right\}$$

(iv) Hardy's formula (5 ordinates)

$$\int_{a}^{b} f(x)dx = \frac{b-a}{6} \left\{ 0.28[f(a)+f(b)]+1.62 \left[f\left(\frac{5a+b}{6}\right) + f\left(\frac{a+5b}{6}\right) \right] + 2.2 f\left(\frac{a+b}{2}\right) \right\}$$

(v) Weddle's rule (7 ordinates)

$$\int_{a}^{b} f(x)dx = 0.3 \ h \left\{ [f(a) + f(b)] + 5[f(a+h) + f(a+5h)] + [f(a+2h) + f(a+4h)] + 6f(a+3h) \right\}, \quad h = (b-\alpha)/6$$

(vi) Shovelton's formula (11 ordinates)

$$\int_{a}^{b} f(x)dx = \frac{5h}{126} \left\{ 8[f(a) + f(b)] + 35[f(a+h) + f(a+3h) + f(a+7h) + f(a+9h)] + 15[f(a+2h) + f(a+4h) + f(a+6h) + f(a+8h)] + 36f(a+5h) \right\}, \quad h = (b-a)/10$$

For other formulae using external ordinates and the values of the multiplying co-efficients, see Table 15.1.

f. Summation formulae

Summation formulae given here are also useful for numerical integration

(i) Euler-Maclaurin sum formula.

$$f(a)+f(a+h)+...+f(a+nh)$$

$$= \frac{1}{h} \int_{a}^{a+na} f(t)dt + \frac{1}{2} [f(a)+f(a+nh)] + \sum_{s=0}^{n} e_{s} h^{2s} \left[\frac{d^{2s+1}}{dt^{2s+1}} f(t) \right]_{a}^{a+nh}$$

where $e_s = B_{2(s+1)}/2(s+1)$! and B_n are Bernoulli numbers given in Table 17.9. with the first few coefficients as follows, $e_0 = \frac{1}{12}$, $e_1 = -\frac{1}{720}$, $e_2 = \frac{1}{30240}$, $e_3 = -\frac{1}{1209600}$, In practice, only the first two or three terms in the last summation need be considered

Gregory's sum formula

$$f(a)+f((a+h)+\ldots+f(a+nh)$$

$$= \frac{1}{h} \int_{a}^{a+nh} f(t)dt + \frac{1}{2} [f(a) + f(a+nh)] + \sum_{s=1}^{\infty} g_s \left[\Delta^s f(a + n-sh) + (-1)^s \Delta^s f(a) \right]$$

where the coefficients g_s , are given by $\sum\limits_{s=0}^{\infty} \ g_s \ t^s = t/\log \ (1-t)$ and the first few coefficients are as follows $g_1 = \frac{1}{12}$, $g_2 = \frac{1}{24}$, $g_3 = \frac{19}{720}$, $g_4 = \frac{3}{160}$, $g_5 = \frac{863}{60480}$, $\overline{24192}$

- Solution of equations by algebraic methods.
- Quadratic equation

The roots of $ax^2+bx+c=0$ are

$$x_1 = \frac{-b + \sqrt{b^2 - 4ac}}{2a}, x_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

(ii) Cubic equation

The general cubic may be written

$$x^3 + c_1 x^2 + c_2 x + c_3 = 0. (1)$$

Setting $x = \dot{y} - \frac{1}{3}c_1$, the equation takes the simple form

$$y^3 + py + q = 0 (2)$$

where $p = c_2 - \frac{1}{3}c_1^2$, $q = c_3 - \frac{1}{3}c_1c_2 + \frac{2}{27}c_1^3$. The roots of (2) are obtained by subtracting $c_1/3$ from each of the roots of (2). The roots of the reduced equation (2) are all real if $q^2+(4/27)p^3<0$. In such a case find a value of θ using Table 17.7 such that

$$\sin 3\theta = -4q/r^3 \tag{3}$$

where $r=2\sqrt{-p/3}$. If $\theta=\alpha$ is a solution of (3), then the three roots of (2) are

$$y_1 = -r \sin \alpha$$
, $y_2 = r \sin \left(\frac{\pi}{3} + \alpha\right)$, $y_3 = r \sin \left(-\frac{\pi}{3} + \alpha\right)$. (4)

When $q^2+(4/27)p^3>0$, two of the roots are imaginary Let Q denote any one of the three values of

$$\left\{\frac{1}{2}(-q+\sqrt{q^2+(4/27)p^3})\right\}^{\frac{1}{3}} \qquad \dots (5)$$

and ω be an imaginary cube root of unity. Then the three roots of (2) are

$$y_1 = Q - p/3Q, \ y_2 = \omega Q - \omega^2 p/3Q, \ y_3 = \omega^2 Q - \omega p/3Q.$$
 (6)

(iii) Quartic equation

The general quartic equation is written

$$ax^4 + 4bx^3 + 6cx^2 + 4dx + e = 0. (7)$$

First find a root of the cubic

$$s^{3} - 3cs^{2} + (4bd - ae)s + 3(ace - 2ad^{2} - 2eb^{2}) = 0 ... (8)$$

by the method indicated in (ii). Let s_1 be a root. Then compute $t_1 = (s_1 - c)/2$,

$$m_1 = \sqrt{at_1 + b^2 - ac}, \ n_1 = (2bt_1 + bc - ad)/m_1.$$
 (9)

Then the four roots of the equation (7) are the roots of the two quadratics

$$\begin{array}{c}
ax^{2} + 2bx + c + 2t_{1} = 2m_{1}x + n_{1} \\
ax^{2} + 2bx + c + 2t_{1} = -(2m_{1}x + n_{1})
\end{array} \qquad \dots (10)$$

Note: Polynomial equations of higher degree than 4 cannot be solved by algebraic reduction. The roots have to be found numerically by methods of successive approximations. The following book may be consulted for such methods.

J. B. Scarborough (1962). Numerical mathematical analysis. 5th, edition, Johns Hopkins Press, Baltimore.

PART II

TABLES WITH EXPLANATORY NOTES

THE BINOMIAL DISTRIBUTION

THE BINOMIAL COEFFICIENTS $\binom{n}{r}$

Introduction

Table 1.1 contains values of
$$\binom{n}{r} = \frac{n!}{r!(n-r)!}$$
, $n = 3(1)30$, $r = 2(1)[n/2]$.

The following formulae help to obtain $\binom{n}{r}$ for the values of r that are not given in Table 1.1.

$$\begin{pmatrix} n \\ 0 \end{pmatrix} = 1, \begin{pmatrix} n \\ 1 \end{pmatrix} = n \text{ and } \begin{pmatrix} n \\ r \end{pmatrix} = \begin{pmatrix} n \\ n-r \end{pmatrix}$$

Application b.

Table 1.1 can be used for computing individual terms $b(x \mid \pi, n) = \binom{n}{x} \pi^x (1-\pi)^{n-x}$ of the binomial distribution.

Example. Let $n=10, \ \pi=0.73;$ then $\theta=\pi/(1-\pi)=2.70370.$ The tabular scheme below shows the essential steps in computation. The first entry in column (3) The values which follow are obtained by successive multiis $(1-\pi)^{10} = 0.05205891$. plication with θ .

x .	(n) *	$\pi^x(1-\pi)^{n-x}$	$b(x \pi,n)$		
(1)	(2)	(3)	$(4) = (2) \times (3)$		
		0.05205891	0.0000		
0	10	0.05556667	0.0001		
1	10	0.04150506	0.0007		
2	45	0.04406923	0.0049		
3	120 210	0.03110020	0.0231		
5	252	0.03297461	0.0751		
	210	0.03804245	0.1689		
3	120	0.02217444	0.2609		
· .7	45	0.02587903	0.2646		
8	10	0.0158951	0.1589		
9 10	10	0.0429756	0.0430		

^{*} From Table 1.1.

If accuracy upto k places of decimal is required in $b(x | \pi, n)$, it is advisable to calculate both $(1-\pi)$ and θ correct to (k+2) significant digits and to retain (k+2) significant digits at each stage in column (3)

The table of binomial coefficients is also useful in computing:

(i) multinomial coefficients, since

$$\frac{n!}{r_1! \; r_2! \; \cdots \; r_k!} = \left(\begin{array}{c} n \\ r_1 \end{array} \right) \times \left(\begin{array}{c} n - r_1 \\ r_2 \end{array} \right) \times \; \cdots \; \left(\begin{array}{c} r_{k-1} + r_k \\ r_{k-1} \end{array} \right)$$

(ii) the individual terms of the hypergeometric distribution, given by

$$\left(\begin{smallmatrix} a\\r \end{smallmatrix}\right)\times \left(\begin{smallmatrix} b\\n-r \end{smallmatrix}\right) \div \left(\begin{smallmatrix} a+b\\n \end{smallmatrix}\right)$$

(1) For higher values of $n\leqslant 100$ see, Tables of Binomial Coefficients by J. C. P. Miller, Cambridge university Press, 1954. Note: Values of $\binom{n}{r}$ are given for r=1,2,... For higher values of r observe that $\binom{n}{r}$

1.2. INDIVIDUAL TERMS

a. Introduction

Table 1.2 gives, to five places of decimal, the values of $b(x \mid \pi, n)$ = $\binom{n}{x} \pi^x (1-\pi)^{n-x}$, x = 0(1)n for n = 5(1)15, and for the following selected values of π :

$$0.01, 0.02, 0.05, \frac{1}{16}, 0.10, \frac{1}{9}, \frac{3}{16}, 0.20, \frac{1}{4}, 0.30, \frac{1}{3}, 0.40, \frac{7}{16}, \frac{4}{9}, \frac{1}{2}$$

Note that since $b(x|\pi, n) = b(n-x|1-\pi, n)$ the coverage is automatically extended to the following additional values of π :

$$\frac{5}{9}$$
, $\frac{9}{16}$, 0.60, $\frac{2}{3}$, 0.70, $\frac{3}{4}$, 0.80. $\frac{13}{16}$, $\frac{8}{9}$, 0.90, $\frac{15}{16}$, 0.95, 0.98, 0.99.

The fractions correspond to values which occur in genetical studies. The values 0.01, 0.02, 0.05 correspond to critical levels generally used in tests of significance.

Table 1.2 has been obtained by differencing from a table of cumulative probabilities which is correct to 5 places of decimals. Some entries in this table are therefore in error by ± 1 in the last place; this is indicated respectively by — or + sign against the entry.

b. Interpolation in Table 1.2

The following formula based on Taylor expansion could be used for interpolating at a specified value of π . Let π_0 be a tabular argument closest to π . Then

$$b(x \mid \pi, n) = b(x \mid \pi_0, n) - dn\Delta \ b(x-1 \mid \pi_0, n-1)$$

$$+ \frac{d^2}{2!} n(n-1)\Delta^2 \ b(x-2 \mid \pi_0, n-2) + \cdots$$

$$+ \frac{(-d)^k}{k!} (n)_k \Delta^k b (x-k \mid \pi_0, n-k) + R$$

where

$$d = \pi - \pi_0, (n)_k = n(n-1) \dots (n-k+1),$$

$$R = \frac{d^{k+1}}{(k+1)!} (n)_{k+1} \Delta^{k+1} b(x-k-1) | \pi^*, n-k-1)$$

 π^* being some intermediate value between π and π_0 and Δ , Δ^2 , ... represent differences of successive order taken with respect to x.

Example 1. To compute $b(2|\pi, n)$ for n = 10, $\pi = 0.27$. Here $\pi_0 = 0.25$, d = 0.02.

$$b(2 \mid 0.27, 10) = 0.28156 - 0.02 \times 10(0.30034 - 0.22526)$$

$$+ \frac{(0.02)^2}{2} \times 10 \times 9(0.31146 - 2 \times 0.26697 + 0.10011)$$

$$= 0.28156 - 0.2 \times 0.07508 + 0.018(-0.12237) = 0.26434.$$

Example 2. Out of 10 tests carried out on parallel sets of data, 3 were significant at 1% level. Are the results significant on the whole?

To answer this question we have to determine the probability of obtaining 3 or more significant results, i.e. the probability of obtaining 3 or more successes in 10 trials when the probability of success at each trial is 0.01. Using Table 1.2, for n = 10 and n = 0.01 the required probability is

$$1-[\Pr(x=0)+\Pr(x=1)+\Pr(x=2)]$$

$$=1-(0.90438+0.09135+0.00416)=0.00011$$

which is very small indicating that the results are significant on the whole. If only one were significant out of ten, then the probability

$$1 - 0.90438 = 0.09562$$

is not small enough to declare overall significance.

Table 1.2 is not exhaustive. For other values of π , for higher accuracy or for higher values of n, one may either consult more extensive tables or compute the values directly as illustrated in 1.1b

c. Some other tables

1. NATIONAL BUREAU OF STANDARDS (1950): Tables of the Binomial Probability Distribution, Applied Math. Series No. 6, Washington.

Individual terms and cumulative sums (cumulated from above) correct to 7 places for $\pi = 0.01$ (0.01) 0.50 and n = 2(1)49.

- 2. Romic, H. G. (1953): 50-100 Binomial Tables, John Wiley & Sons, New York and London. Individual terms and cumulative sums (cumulated from below) correct to 6 places for $\pi = 0.01$ (0.01) 0.50 and n = 50(1)100.
- 3. U. S. Army Ordnance Corps (1952): Tables of the Cumulative Binomial Probabilities, Ordnance Corps Pamphlet ORDP 20-1.

Cumulative sums (cumulated from above) correct to 7 places for $\pi = 0.01(0.01)~0.50$ and n = 1(1)150.

HARVARD UNIVERSITY, COMPUTATION LABORATORY (1955): Tables of the Cumulative Binomial Probability
Distribution, The Annals of the Computation Laboratory of Harvard University, 35, Cambridge
(Massachussetts).

Cumulative sums (cumulated from above) correct to 5 places for $\pi = 0.01(0.01) \ 0.50 \cdot 1/12(1/12) 5/12; 1/16(1/16) 7/16 and <math>n = 1(1) \ 50(2) \ 100(10) \ 200(20) \ 500(50) \ 1000.$

5. WEINTRAUB, S. (1963): Tables of the Cumulative Binomial Probability Distribution for Small Values of p, The Free Press of Glencoe, Collice—Macmillan Ltd., London.

Cumulative sums (cumulated from above) correct to 10 places for $\pi = 0.00001$, 0.0001 (0.0001) 0.0010 (0.0010) 0.1000 and n = 1(1)100.

Note: To obtain 5 decimal accuracy for individual terms add (subtract) 1 in the last place if there is +(-) sign against an entry. For obtaining cumulative probabilities to 5 decimal accuracy the entries have to be added ignoring the + and - signs.

1.3. Confidence Intervals For The Binomial Proportion

a. Introduction

Table 1.3 furnishes two sided 95+% and 99+% confidence limits for the unknown binomial proportion π , corresponding to the number of trials n and the observed value of x.

These confidence limits have the property, that compared to any other system of limits with confidence coefficients not less than 95%, and 99%, the total length of confidence intervals corresponding to x = 0, 1, ..., n is the least. For details see Crow (1956, Biometrika, 43, 423-435) and Sterne (1954, Biometrika, 41, 275-278).

The confidence limits given in Table 1.3 are correct to three places of decimal and are for n = 1/1)30 and x = 0(1)[n/2]. If x is greater than $\lfloor n/2 \rfloor$, n-x would be $\leq \lfloor n/2 \rfloor$, and the table can be read for confidence limits for the complementary proportion $(1-\pi)$ from which the confidence limits for π are obtained.

Example. Suppose n=25 and x=14. Then n-x=11. Entering Table 1.3 with x=11 and n=25 the 95% limits for $1-\pi$ are seen to be (0.238, 0.664) which means that the 95% limits for π would be (1-0.664, 1-0.238)=(0.336, 0.762).

b. One sided confidence intervals

The $100\alpha\%$ lower bound for π is the smallest value of π , satisfying the inequality $P(d; \pi, n) = \sum_{x=d}^{n} b(x|\pi, n) \geqslant 1-\alpha$, where d is the observed value of x.

Since
$$Q(d; \pi, n) = \frac{1}{B(d, n-d+1)} \int_{0}^{\pi} t^{d-1} (1-t)^{n-d} dt$$
,

this lower bound is seen to be the lower $100(1-\alpha)$ % point of the beta distribution with parameters d and n-d+1 respectively. (See Table 6.2 for percentage points of the beta distribution). Similarly the $100\alpha\%$ upper bound on π is given by the upper $100(1-\alpha)$ % point of the beta distribution with parameters d+1 and n-d respectively.

c. Tests of significance

Table 1.3 can also be used for testing a simple hypothesis on π , when alternatives are both-sided. If x = d be the observed value of x in n trials, we find, from Table 1.3 the corresponding $100\alpha\%$ confidence interval for π . A null hypothesis which assigns a value of π outside the confidence interval is rejected at the $100(1-\alpha)\%$ level of significance.

Example. 18 tosses of a coin result in 5 heads. Is this compatible with the hypothesis that the coin is unbiased?

Here n=18, x=5. The corresponding 95% confidence interval for π being (0.116, 0.556), the hypothesis $\pi=0.5$ cannot be rejected at the 5% level of significance.

Table 6.2 (percentage points of the beta distribution) can be similarly used for testing a simple hypothesis on π , when alternatives are one-sided. Suppose in the above example the hypothesis $\pi=0.5$ is to be tested against alternatives $\pi<0.5$. The 95% upper bound for π (which is same as the upper 5% point of B(6, 13))=0.4978. Since the hypothetical value exceeds this value, the hypothesis stands rejected at the 5% level of significance.

2.1 CUMULATIVE PROBABILITY

a. Introduction

Let $p(x|\lambda) = e^{-\lambda} \frac{\lambda^x}{x!}$ (probability for observation x) and $P(x|\lambda) = \sum_{r=0}^{x} p(r|\lambda)$ (cumulative probability for observations up to x). Table 2.1 gives the values $P(x|\lambda)$, x = 0, 1, 2, ... for $\lambda = 0.02(0.02)\ 0.10$; $0.15(0.05)\ 1.00$; 1.1(0.1)2.0, 2.2(0.2)7.8; 8.0(0.5) 15.0; 16(1)25. Table 2.1a gives the values of $P(x|\lambda)$ for small values of $\lambda = 0.0005$; 0.001(0.001)0.009. The individual terms $p(x|\lambda)$ can be easily obtained from these tables by the relation $p(x|\lambda) = P(x|\lambda) - P(x-1|\lambda)$

b. Interpolation in Table 2.1

For purposes of interpolation (λ -wise) between the tabulated values the following formula based on Taylor expansion will be found useful. Let the values of $P(\hat{x} \mid \lambda)$ be required for a given λ , and λ_0 stand for the tabular argument closest to λ , and let $d = \lambda - \lambda_0$. Then

$$P(x \mid \lambda) = P(x \mid \lambda_0) - d\Delta P(x - 1 \mid \lambda_0) + \frac{d^2}{2!} \Delta^2 P(x - 2 \mid \lambda_0) + \dots + (-1)^k \frac{d^k}{k!} \Delta^k P(x - k \mid \lambda_0) + R$$

where Δ , Δ^2 ... are the 1st, 2nd...order differences taken with respect x and $R = (-1)^{k+1} \frac{d^{k+1}}{(k+1)!} P(x-k-1 | \lambda^*)$ where λ^* is some value lying between λ and λ_0 . It will be thus-possible to judge, by inspection of the tabulated values, the maximum possible magnitude for the error R.

Example

To compute P(4|5.1)

From Table 2.1, $\lambda_0=5.0$ so that d=0.1 Omitting terms involving second and higher order differences

$$P(4 \mid 5.1) = 0.440 - 0.1(0.440 - 0.265) = 0.4225$$

$$R = (-1)^2 \frac{(0.1)^2}{2!} \Delta^2 P(2|\lambda^*)$$
 where $5.0 < \lambda^* < 5.1$

Since $\Delta^2 P(2|5) = 0.035$, $\Delta^2 P(2|5.2) = 0.039$, $\Delta^2 P(2|5.4) = 0.042$ and Δ^2 increases with λ

$$0 < R < \frac{(0.1)^2}{2} \times 0.039 = 0.000195.$$

When the interpolation for a given value of λ has to be repeated, as for instance in fitting a Poisson distribution, the above formula may be written as follows

(i) linear interpolation

$$P(x|\lambda) = (1-d)P(x|\lambda_0) + dP(x-1|\lambda_0)$$

(ii) quadratic interpolation

$$P(x|\lambda) = (1 - d + d^2/2) P(x|\lambda_0) + (d - d^2)P(x - 1|\lambda_0) + \frac{d^2}{2} P(x - 2|\lambda_0)$$

Enample

Fit a Poisson law to the frequency distribution of number of defects in 377 metal sheets produced in a factory.

No. of defects	Number of sheets	Poisson frequency
0	181	190.4
1	142	129.9
2	47	44.6
2	6	10.0
4	1	1.8
5 and above	· · · · · · · · · · · · · · · · · · ·	0.3
Total	377	377.0

The mean of the observed frequency distribution is 0.684 which provides an estimate for λ of the Poisson distribution to be fitted. The nearest tabular argument λ_0 in Table 2.1 is 0.70 so that d=-0.016. Using the formula for linear interpolation P(0|0.684)=0.504952, P(1|0.6849)=0.849552, P(2|0.684)=0.967952, P(3|0.684)=0.994448, P(4|0.684)=0.999080 and P(5|0.684)=1.0. The values of p(x|0.684) for x=0,1,2,3,4,5 are 0.5050, 0.3446, 0.1184, 0.0265, 0.0046, 0.0009. The Poisson frequencies obtained by multiplying these by 377 are shown in the last column above.

Table 2.1 is particularly useful in working out the operating characteristic curves of acceptance sampling plans by attributes. Poisson distribution is also applicable in a variety of industrial and other situations such as number of accidents, defects in cloth, defects in castings, frequency of breakdown of machines, demand for spares etc.

c. Some other tables of the Poisson distribution

 MOLINA, E. C. (1942): Poisson's Exponential Binomial Limit, Van Nostrand Book Company, New York.

Individual terms and cumulative terms of the distribution, correct to 6 and 7 places for $\lambda = 0.001 (0.001)9.01 (0.01)3.01(1.11)100$.

For small values of π and large values of n (for $\pi < 0.10$ and definitely for $n \pi < 5$) the binomial distribution is better approximated by the Poisson distribution than by the normal distribution. For example to find the probability of getting 5 or less defectives in a sample of 200 items from a process with fraction defective 0.02, we have $n\pi = 0.02 \times 200 = 4$. From Table 2.1 for $\lambda = 4$ and x = 5, the required probability is 0.785 which is close to the true value of 0.78672.

For large values of λ , the following normal approximation may be used.

$$P(x \mid \lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{(x+0.5-\lambda)/\sqrt{\lambda}} e^{-t^2/2} dt.$$

For example to find $P(x|\lambda)$ for $\lambda = 25$ and x = 27, we have

$$\frac{x+0.5-\lambda}{\sqrt{\lambda}} = \frac{27+0.5-25}{5} = 0.5$$

From Table 3.1, the probability for normal deviate 0.5 is 0.500000+0.191462 = 0.691462, which is close to the true value of $P(x|\lambda) = 0.700$

There exists an exact relationship between cumulative Poisson probability and the probability integral of the X^2 distribution, i.e.

$$P(x \mid \lambda) = 2^{-\nu/2} \left\{ \Gamma(\nu/2) \right\}^{-1} \int_{21}^{\infty} e^{-\frac{1}{2}u} u^{\frac{\nu}{2}-1} du.$$

$$\nu = 2(x+1)$$
 for $x = 0, 2, \dots$ etc.

2.2. CONFIDENCE INTERVALS FOR THE POISSON MEAN

a. Introduction

Table 2.2 gives two sided 95+% and 99+% confidence limits for the Poisson parameter λ (which is the mean of the Poisson distribution) based on a single observation x. Since the sum of n independent Poisson variables is also distributed according to the Poisson law with parameter $n\lambda$, we can find, by considering the sum of the observations as the variable, the confidence interval for $n\lambda$ and hence for λ , when there are n observations from the Poisson distribution.

The confidence intervals given in Table 2.2 follow the same principle as mentioned in 1.3a and are based on tables provided by Crow and Gardner (1959).

The limits in Table 2.2 are given correct to two places of decimal, for values of x = 0(1)50. For higher values of x one may use the following limits derived from the normal approximation to the Poisson distribution

confidence coefficient	lower limit	upper limit
0.95	$x-1.96 \sqrt{x}$	$x+1.96 \sqrt{\tilde{x}}$
0.99	$x-2.58\sqrt{x}$	$x+2.58 \sqrt{\widetilde{x}}$

Example. A total number of 30 seeds were observed in a sample of n=20 glass sheets manufactured by a certain process. It is required to find the 95% confidence interval for the process average number λ of seeds per sheet.

Entering Table 2.2 with x=30 the 95% limits for $n\lambda$ (n=20 in this example) are read as (20.33, 41.75). For these the 95% confidence limits for the process average number (λ) of seeds per sheet are given by

$$\left(\frac{20.33}{20}, \frac{41.75}{20}\right)$$
 or $(1.02, 2.09)$.

b. One sided confidence limits

With c as the observed value of x, the $100\alpha\%$ lower bound on λ is the smallest value of λ that satisfies the inequality

$$Q(c \mid \lambda) = \sum_{x=c}^{\infty} p(x \mid \lambda) \geqslant 1 - \alpha.$$

Since

$$Q(c \mid \lambda) = \int\limits_0^{\lambda} \frac{e^{-t} \ t^{c-1}}{\Gamma(c)} \ dt$$

the $100\alpha\%$ lower bound for λ is seen to coincide with half the value of the lower $100(1-\alpha)\%$ point of the chi-square distribution with 2c degree of freedom (Table 5.1).

Similarly the 100α % upper bound for λ is given by U/2 where U is the upper $100(1-\alpha)$ % point of the chi-square distribution with (2c+2) degrees of freedom,

Example. The upper 5% point of chisquare with 62 d.f. is 81.4. Hence with the same data as in the earlier example one may assert with 95% confidence that the average number of seeds per manufactured sheet does not exceed $\frac{1}{20} \times \frac{1}{2} \times 81.4 = 2.035$.

c. Tests of significance

Table 2.2 can be used for testing a simple hypothesis regarding λ when alternatives are both-sided. A hypothesis is rejected when the value of λ it specifies falls outside the confidence interval corresponding to the observed value of x.

Table 5 would similarly be useful for one sided tests on λ .

3. THE STANDARD NORMAL DISTRIBUTION

3.1. ORDINATES AND PROBABILITY INTEGRAL

a. Introduction

Table 3.1 provides, correct to six places of decimal, values of the ordinates of the standard normal distribution

$$N(x) = N(x|0,1) = \frac{1}{\sqrt{2\pi}}e^{-x^2/2}, x = 0(0.01) 3 (0.1) 4$$

and the values of the probability integral

$$P(x) = \int_0^x N(w)dw \text{ for } x = 0(0.001) \ 3 \ (0.01) \ (0.1) \ 4.9.$$

From symmetry N(x) = N(-x) and for non-negative numbers a and b, (a < b)

$$\int_{a}^{b} N(w)dw = P(b) - P(a) = \int_{-b}^{-a} N(w)dw$$

$$\int_{-a}^{b} N(w)dw = P(b) + P(a) = \int_{-b}^{a} N(w)dw$$

Example. The score S in a certain test is known to be mormally distributed with mean 50 and standard deviation 10. Determine the proportion of cases for which the scores lie between (i) 35 and 55, and (ii) 55 and 67.

The distribution of w = (S-50)/10 is standard normal. Hence for (i) the answer is $\int_{-1.5}^{0.5} N(w)dw = P(0.5) + P(1.5) = 0.191462 + 0.433193 = 0.624655$.

Similarly the answer for (ii) is

$$\int_{0.5}^{1.7} N(w)dw = P(1.7) - P(0.5) = 0.455435 - 0.191462 = 0.263973.$$

b. Derivatives of N(x)

The Tchebycheff-Hermite polynomials $H_i(x)$ are defined by equations

$$\frac{d^r N(x)}{dx^r} = (-1)^r H_r(x) N(x)$$

The table below gives the coefficients in $H_r(x)$ for r upto 10

COEFFICIENTS IN HERMITE POLYNOMIALS

r	æ	æ3	æ5.	x7	259
1	1				
3	-3	1	•		
5	15	-10	· 1	•	
7	-105	105	-21	1	•
9	945	-1260	378	-36	1

r	x^0	x^2	v^4 .	æc	x3	x10
2	-1	. 1				
4	3	· —6	1			
6	-15	45	-15	1		. 1
8	105	-420	210	28		
10	-945	4725	-3150	630	45	1

c. Direct interpolation in Table 3.1

Formulae for interpolation are derived from the following Taylor expansions:

$$\begin{split} N(x) &= N(x_0) \left[1 - aH_1(x_0) + \frac{a^2}{2} H_2(x_0) - \frac{a^3}{6} H_3(x_0) + \dots \right] \\ &= N(x_0) \left[1 - ax_0 + \frac{a^2(x_0^2 - 1)}{2} - \frac{a^3(x_0^3 - 3x_0)}{6} + \dots \right] \\ P(x) &= P(x_0) + N(x_0) \left[a - \frac{a^2}{2} H_1(x_0) + \frac{a^3}{6} H_2(x_0) - \dots \right] \\ &= P(x_0) + N(x_0) \left[a - \frac{a^2x_0}{2} + \frac{a^3(x_0^2 - 1)}{6} - \dots \right] \end{split}$$

where x_0 denotes the tabular argument nearest to x for which answer is required and $a = x - x_0$.

For N(x), the maximum error in using upto linear terms (linear in a) is $0.1995a^2$ and upto quadratic terms is $0.0918a^3$. For P(x) the maximum error in using upto linear terms only is $0.1210a^2$ and upto quadratic terms, is $0.0665a^3$.

Example 1. Determine N(0.0149)

Choosing $x_0 = 0.01$, we have a = 0.0049. Then

$$N(.0149) = N(x_0) \left[1 - ax_0 + \frac{a^2(x_0^2 - 1)}{2} \right]$$

$$= 0.398922(1 - 0.000049 - 0.000012) = 0.398898 \text{ (to 6 decimal places)}$$

Example 2. Determine P(1.0236)

We use a slightly different formula for interpolation of P(x),

$$P(x) = P(x_0) + N(x_0^{\bullet}) \left[a - \frac{a^2x}{2} \right]$$

where x_0 is the tabular argument closest to x and x_0^* is x_0 rounded to two places of decimals. The substitution of $N(x_0^*)$ for $N(x_0)$ in the original formula does not introduce any serious error and the accuracy of this formula is comparable to the one considered earlier. Choosing $x_0 = 1.024$, we have a = -0.0004, and $x_0^* = 1.02$.

$$P(1.0236) = 0.349432. + 0.237132 \times [-0.0004]$$

= $0.349432 - 0.000095 = 0.349337$ (to 6 places).

d. Inverse interpolation

Then

Suppose it is required to find x corresponding to a given value of P(x) = A, between two consecutive tabular entries in Table 3.1. Let x_0 be the argument corresponding to the nearest entry. The following formula determines x correct to five places of decimal for $x \le 1.1.663$ and at least to four decimal places elsewhere:

$$x = x_0 + \frac{A - P(x_0)}{N(x_0)}$$
.

Example 3. Determine x for which P(x) = 0.25.

As in the formula for P(x) in example 2, the above formula can be rewritten as

$$x = x_0 + \frac{A - P(x_0)}{N(x_0^*)}$$
.

Choosing $x_0 = 0.674$, we have $x_0^* = 0.67$. Then $x = 0.674 + \frac{.000156}{0.318737} = 0.674 + 0.0049$ = 0.67449 (to 5 decimal places).

e. Some other tables

I. [U.S.] NATIONAL BUREAU OF STANDARDS (1953): Tables of Normal Probability Functions, Applied Mathematics Series 23, Washington

Table I gives N(x) and $\int_{-x}^{x} N(w)dw$ correct to 15 places of decimal for x = 0(0.0001)1(0.001)

7.800 (various) 8.285. Table II gives N(x) and $\int_{-x}^{x} N(w)dw$ correct to 7 significant figures 6(0.01) 10.

3.2. PERCENTAGE POINTS

a. Introduction

For various values of p, Table 3.2 provides the upper 100p% points of the absolute value of the standard normal variable, or more explicitly it gives the value of x satisfying the equation

$$p = \int_{x}^{\infty} N(w)dw + \int_{-\infty}^{-x} N(w)dw = 2 \int_{x}^{\infty} N(w)dw$$

Since $\frac{p}{2} = \int_{x}^{\infty} N(w)dw$, the tabular values may also be interpreted as the upper 50p% point of the standard normal variable. The lower 50p% point can be obtained by prefixing a negative sign to the value of the upper 50p% point. Thus reading against p = .24 in Table 3.2, the upper 12% point of the standard normal variable is obtained as 1.174987. The lower 12% point is therefore -1.174987.

Table 3.2 also provides a short table of p (the probability of an observation falling outside the range -x to x) for the following values of x

$$x = 0.25, 0.5(0.5) 5.0.$$

b. Application

Table 3.2 is useful in tests of significance. particularly in large sample tests using standard errors (see Chapter IV in Part I) and together with Table 3.1, in a limited sense, for probit analysis. A further use is in Cornish-Fisher type expansions for the fractiles of other variables having asymptotically a standard normal distribution. For t, F and X^2 these expansions are provided in explanatory notes preceding the corresponding tables.

^{(1):} The first digit of p after the decimal point is given in the column and the second digit in the row:

4. THE -DISTRIBUTION

a. Introduction

Table 4.1 gives the p-th fractile of the t-distribution, for degrees of freedom $v = 1(1)30, 40(20)100, \infty$, the values of p being:

Fractiles for the following values of p can also be easily deduced from Table 41, by changing sign because of symmetry (about the origin) of the t-distribution:

$$p:0.0005,\ 0.001,\ 0.005,\ 0.01,\ 0.025,\ 0.05,\ 0.1,\ 0.15,\ 0.2,\ 0.25,\ 0.3,\ 0.4.$$

Example: To find the fractile of t for v = 4, p = 0.05.

The required fractile is -2.132 (2.132 being the 0.95-th fractile of t for 4 degrees of freedom).

The last six columns of Table 4.1 directly provide critical values of |t| for two-sided tests at the 10%, 5% and 2%, 1%, 0.2% and 0.1% levels of significance respectively. They also give the critical values of t for upper tail tests at the significance levels of 5%, 2.5% and 1%, 0.5%, 0.1% and 0.05%. A negative sign prefixed to these values would provide the critical values for lower tail tests.

3. Computing the fractiles for other degrees of freedom

For higher values of ν Cornish-Fisher expansion of t_p (the p-th fractile of t with ν d.f.) may be used to determine its value to any desired accuracy

$$t_{p_{\nu}} = x + \frac{1}{\nu} \left(\frac{x^{3} + x}{4} \right) + \frac{1}{\nu^{2}} \left(\frac{5x^{5} + 16x^{3} + 3x}{96} \right) + \frac{1}{\nu^{3}} \left(\frac{3x^{7} + 19x^{5} + 17x^{3} - 16x}{384} \right) + \frac{1}{\nu^{4}} \left(\frac{79x^{9} + 776x^{7} + 1482x^{5} - 1920x^{3} - 945x}{92160} \right) + \dots$$

where x is the p-th fractile of the standard normal distribution.

Values of x (the first term) and the coefficients of $1/\nu$, $1/\nu^2$, etc. in the expansion, for the different values of p covered in Table 4.1 are shown below

COEFFICIENTS* IN THE CORNISH-FISHER EXPANSION

				,	va	lue of p

1/v4	1.6	12.1	79.4	0.4	5.6	48.6	0	0.	0	0	0.1

^{*} Sufficient figures are retained to ensure accuracy in the fourth decimal place for n > 30.

The coefficients for p = 0.85 of 1, $1/\nu$, $1/\nu^2$, $1/\nu^3$ and $1/\nu^4$ are 1.03643, 0.53744, 0.28023, 0.078 and 0.0 respectively.

c. Applications

Some uses of Table 4.1 are illustrated

(i) One sample problem-test and confidence interval

Example: The mean and sample variance of hardness (Rockwell E) determined from a sample of 10 pieces of die-cast aluminium are:

$$\bar{x} = 68.5$$
 $s^2 = \frac{\sum (x_i - \bar{x})^2}{n-1} = 2.5.$

Are these consistent with the hypothesis that the average hardness μ in respect of the manufacturing process is 70 ?

$$t = \frac{x-\mu}{s/\sqrt{n}} = -3.0$$
, and $|t| = 3.0$.

The 5% and 1% level values of |t| (for a two-sided test) for 9 d.f. being 2.262 and 3.250 respectively, the hypothesis can be rejected at the 5% level. On the basis of the data a 95% confidence statement of the following kind can be made:

(a)
$$\mu$$
 does not exceed $x+1.833 \frac{s}{\sqrt{10}} = 69.42$,

or (b)
$$\mu$$
 does not fall below $x-1.833 \frac{s}{\sqrt{10}} = 67.58$,

or (c)
$$\mu$$
 lies between $x-2.262 \frac{s}{\sqrt{10}} = 67.37$ and $x+2.262 \frac{s}{\sqrt{10}} = 69.63$

where 10 under square root in the denominator is the sample size and 1.833, 2.262 are upper 5 % and two-sided 5 % values of t from Table 4.1 corresponding to n-1 (= 9) d.f.

(ii) Two-sample problem

Example: The impact strength readings in foot pounds in samples of sheets from two lots were summarised as follows:

Lot 1: Sample size $n_1 = 8$,

$$x_1 = 0.925, s_1^2 = \frac{\sum (x_{1i} - \bar{x}_1)^2}{n_1 - 1} = .087.$$

Lot 2: Sample size $n_2 = 10$,

$$x_2 = 0.857, s_2^2 = \frac{\sum (x_{2i} - x_2)^2}{n_2 - 1} = .079.$$

Do the lots differ significantly in respect of the average impact strength?

Assuming that the lots are of equal variability,

$$i = (\bar{x}_1 - \bar{x}_2) \div \sqrt{\left(\frac{1}{n_1} + \frac{1}{n_2}\right) \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}} = 0.499$$

The 5% value of |t| with $n_1+n_2-2=16$ d.f. being 2.120, the data do not lead to rejection of the hypothesis that the two lots have the same average impact strength.

(iii) Regression problem

Example: The thickness of zinc coating on 12 pieces of galvanized sheets were determined by the standard stripping method (X) and a magnetic method (Y). The least squares line of regression of Y on X and other statistics were as follows

$$Y = -0.23 + 1.17x$$
.

 $S_{xx} = \Sigma x_i^2 - n\bar{x}^2 = 298,015$, $S_{yy} = \Sigma y_i^2 - n\bar{y}^2 = 410,345$, $S_{xy} = \Sigma x_i y_i - n\bar{x}\bar{y} = 348,915$, $b = S_{xy}/S_{xx} = 1.17$, $R_0^2 = \text{Residual sum of squares} = S_{yy} - S_{xy}^2/S_{xx} = 1,836$. Test if the regression coefficient is significantly higher than 1 at the 1% level.

$$t = (b-1) \div \sqrt{\frac{R_0^2}{(n-2)S_{xx}}} = (1.17-1) \div \sqrt{\frac{1836}{10 \times 298015}} = 6.849.$$

The upper 1% value of t with n-2=10 d.f. being 2.764, the observed regression coefficient is seen to be significantly higher than 1 at the 1% level.

(iv) Significance of the correlation coefficient

Example: Is a correlation of r = 0.52 between green weight and yield of jute fibre, observed on 20 jute plants significant?

$$t = \sqrt{n-2} \quad \frac{r}{\sqrt{1-r^2}} = 2.583.$$

The 5% and 1% values of |t| (for two-sided test) with n-2=18 d.f. being 2.101 and 2.878 respectively, the observed correlation is significant at the 5% level but not at the 1% level. (This test is however valid only under the assumption that the joint distribution of the two variables under study is bivariate normal).

5. Some other tables

 Pearson, E. S. and Hartley, H. O. (Eds.) (1957): Biometrika Tables for Statisticians, Biometrika Trust, Cambridge University Press.

Table 9 gives the incomplete probability integral of t for v = 1(1)24,30,40,60,120, ∞ ; t = 0(0.1) 4(0.2) 8 for $v \le 19$ and = 0(0.05) 2 (0.1) 4,5 for $v \ge 20$.

 Federight, E. T. (1959): Extended Tables of the Percentage Points of Student's t-distribution. Jour, Amer. Stat. Assen., Vol. 54, pp. 683-688.

Gives to three 3 places of decimal for the following values p and v.

p = 0.75, 0.90, 0.95, 0.975, 0.99, 0.995, 0.9975, 0.999, 0.9995, 0.99995, 0.999975, 0.999999, 0.999995, 0.999999, 0.999999, 0.9999995, 0.9999999.

v = 1(1)30(5)60(10) 100, 200, 500, 1000, 2000 and 10000.

Note: 1. v represents the degrees of freedom.

- 2. For any given p in the top row, the table provides the value of t_p such that the probability of t being less than t_p is equal to p For p < 0.5, $t_p = -t_{(1-p)}$, $t_{0.50}$ being zero always.
- 3. For tests of significance, use the critical values for different levels of significance indicated in the last two rows. For a two sided test (for significance of |t|) use the levels in the first row. For one sided (upper) test use the levels in the second row. For lower one sided test the critical value is the same as that for the upper tail with the sign changed.

5. THE χ^2 -DISTRIBUTION

a. Introduction

Table 5.1 essentially provides, fractiles of the χ^2 -distribution for degrees of freedom $\nu = 1$ (1) 30 (5) 40 (10) 100, and for values

p = 0.005, 0.01, 0.025, 0.05, 0.25, 0.50, 0.75, 0.95, 0.975, 0.99, 0.995.

Columns (1) and (2) of Table 5.1 gives the lower 1% and 5% values and columns (3) and (4) the upper 1% and 5% values of the distribution of χ^2 . These entries are useful in one sided tests using only the upper or the lower tail.

For a two sided test one may use equal partition of tails at any given level of significance. Columns (5) and (6) provide the acceptable interval of χ^2 at 1% level and, columns (7) and (8) that at 5% level. Values of χ^2 beyond the interval on either side will be declared significant.

Columns (9) to (12) provide an alternative set of partitions of χ^2 at the 1% and 5% levels of significance for two sided tests. These are called unbiased partitions (χ_1^2, χ_2^2) and satisfy the equations

$$e^{-\chi_1^2/2} \chi_1^{\nu} = e^{-\chi_2^2/2} \chi_2^{\nu}$$

$$\frac{1}{2^{\nu/2} \Gamma(\frac{\nu}{2})} \int_{\chi_1^2}^{\chi_2^2} e^{-\chi_2^2/2} (\chi^2)^{\frac{\nu-2}{2}} d\chi^2 = 1 - \alpha = (0.99 \text{ or } 0.95)$$

where ν is the d.f.

The last three columns of Table 5.1 give the first quartile, median and the third quartile of the distribution.

b. Computation of fractiles for other degrees of freedom

The following expansion due to Cornish and Fisher may be used for higher values of v. χ_p^2 and x are the p-th fractiles of χ^2 (with v d.f.) and the standard normal distribution respectively. Then

$$\chi_{p}^{2} = \nu + \sqrt{\nu} \left(x\sqrt{2} \right) + \frac{2}{3} (x^{2} - 1) + \frac{1}{\sqrt{\nu}} \left(\frac{x^{3} - 7x}{9\sqrt{2}} \right)$$

$$- \frac{1}{\nu} \left(\frac{6x^{4} + 14x^{2} - 32}{405} \right) + \frac{1}{\nu\sqrt{\nu}} \left(\frac{9x^{5} + 256x^{3} - 433x}{4860\sqrt{2}} \right)$$

$$+ \frac{1}{\nu^{2}} \left(\frac{12x^{6} - 243x^{4} - 923x^{2} + 1472}{25515} \right)$$

$$- \frac{1}{\nu^{2}\sqrt{\nu}} \left(\frac{3753x^{7} + 4353x^{5} - 289517x^{3} - 289717x}{9185400\sqrt{2}} \right) + \dots$$

Substituting the value of x, from normal tables, χ_p^2 can be computed to the desired degree of approximation. To facilitate the computations, the coefficients of $\sqrt{\nu}$, 1, $1/\sqrt{\nu}$ etc. in the above expansion are given below for p=0.5, 0.75, 0.95, 0.975, 0.99, and 0.995. To compute $\chi_{(1-p)}^2$ we use the same tabulated coefficients as for p but with signs of the first, third and every alternate coefficients changed. Thus one can compute χ_p^2 for also p=0.005, 0.01, 0.025, 0.05 and 0.25 using the tabulated values of the coefficients.

coefficient	·	:	value of p			
of	0.99	0.95	0.995	0.975	0.5	0.75

COEFFICIENTS* IN THE CORNISH-FISHER EXPANSION

Sufficient figures are retained to ensure accuracy upto the fourth decimal place for $30 < v \le 1600$. For values of v > 1600, the figures in the first row have to be computed to a higher number of decimal places.

c. Application

Some examples illustrating the use of Table 5.1 are given below.

(i) Variance of a normal population —tests and confidence intervals

Example. The sample variance of the blowing time of 10 fuses is:

$$s^2 = \sum (x_i - x)^2 / (n - 1) = 384.16$$
 (sec.)².

Is this compatible with the hypothesis that the population variance is $\sigma_0^2 = 300$ (sec)².

Situation 1: Given that the population variance can only equal or exceed 300.

$$\frac{(n-1)s^2}{\sigma_0^2} = \frac{9(384.16)}{300} = 11.5248.$$

From Table 5.1 the upper 5% point of χ^2 with n-1 (= 9) d.f. is 16.92. Thus the hypothesis cannot be rejected.

Situation 2: Direction in which deviation from the hypothetical value can occur is unspecified.

If one chooses to apply an unbiased test, the critical values are 2.95 and 20.31. The computed value of χ^2 is well within this interval. Hence the hypothesis cannot be rejected.

On the basis of the observed value of s², one can make 95% confidence statements of the following kind.

- (a) σ^2 does not exceed $(n-1)s^2/3.33 = 1038.72$
- (b) σ^2 is not less than $(n-1)s^2/16.92 = 294.34$
- (c) σ^2 lies between $(n-1)s^2/20.31 = 170.23$ and $(n-1)s^2/2.95 = 1172.01$
- (d) σ^2 lies between $(n-1)s^2/19.02 = 131.78$ and $(n-1)s^3/2.70 = 1280.53$,

where 3.33 and 16.92 are respectively the lower and upper 5% points, and (2.95, 20.31) and (2.70, 19.02) are respectively the unbiased and equal tail 5% partitions of χ^2 , with 9 d.f.

(ii) Combination of probabilities: To judge the overall significance of several tests.

Example. The following significance levels were attained in 5 independent rests of the same hypothesis: 0.06, 0.06, 0.07, 0.10, 0.09. Considered together, is the evidence strong enough to reject the hypothesis?

The appropriate statistic is

$$P_{\lambda} = -2 \log_{\theta} 10 \sum_{i=1}^{2} \log_{10} p_{i} = 25.993.$$

which, as a χ^2 with 2k (=10) d.f., is significant at the 1% level. Hence, even though individually none of the 5 tests leads to rejection of the hypothesis, with the evidence provided by the five independent tests together, the hypothesis stands rejected.

(iii) Goodness of fit

For other applications of the χ^2 table in test of goodness of fit, test of independence in contingency tables etc., see some standard books on statistical methods.

d. Some other tables

- HALD, A. and SINEBAEE. S. A. (1950): A table of percentage point χ² distribution. Skand Aktuarictidskr, vol. 33, pp. 168-175.
 Gives fractiles to three places of decimal for the following values of p: 0.0005, 0.001, 0.005.
 - 0.01, 0.025, 0.05, 0.1(0.1) 0.9, 0.95, 0.975, 0.99, 0.995, 0.999, 0.9995 and v = I(1)100.
- Halo, A. (1952): Statistical Tables and Formulas, John Wiley & Sons, New York.
 Table V gives fractiles to three figures. Otherwise the coverage is same as in 1. above. Table V1 gives fractiles of χ²/ν correct to four places of decimal for the following values of p: 0.0005, 0.001, 0.005, 0.01, 0.025, 0.05, 0.95, 0.975, 0.99, 0.995, 0.999, 0.9995 and ν= 1(1) 100(5) 200, (10) 300 (50) 1000 (1000) 5000, 10000.
- 3. Pearson, E. S. and Hartley, H. O. (Eds.) (1957): Biometrika Tubles for Statisticians, Biometrica Trust, Cambridge University Press.

Table 7 gives
$$\int_{\chi^2 2^{\nu/2} \Gamma(\frac{\nu}{2})}^{1} \frac{1}{e^{-\nu/2} v^{\nu/2-1} d\nu} \text{ to 5 decimal places for } \nu = 1(1) \ 30(2) \ 70,$$

 $X^2 = 0.001 \ (0.001) \ 0.01 \ (0.01) \ 0.1 \ (0.1) \ 2(0.2) \ 10(0.5) \ 20(1) \ 40(2) \ 134.$

Table 8 gives the fractiles of χ^2 to three and more places of decimal for the following values of p: 0.005, 0.016, 0.025, 0.050, 0.1, 0.25, 0.5, 0.75, 0.9, 0.95, 0.975, 0.995, 0.999 and v = 1(1) 30(10) 100.

Note: For significance X2 should exceed tabulated value for one sided upper tail test, X2 should be less than tabulated value for one sided lower tail test and X2 should be outside tabulated interval for a two sided test.

6. THE F DISTRIBUTION

6.1. FRACTILES

a. Introduction

Table 6.1 gives fractiles of the F distribution for various combinations of v_1 and v_2 , the degrees of freedom of the numerator and denominator mean squares respectively. The values of p and the degrees of freedom covered are:

$$p = 0.25 \ 0.5, \ 0.75, \ 0.95, \ 0.975, \ 0.99, \ 0.995$$

 $v_1 = 11(1)9, \ 12, \ 24, \ \infty$
 $v_2 = 1(1)30, \ 40, \ 60, \ 120, \ \infty$.

If F_p (v_1 , v_2) denotes the p-th fractile, then we have the relation F_{1-p} (v_1 , v_2) = $1/F_p(v_2, v_1)$, so that Table 6.I can be used to obtain the fractiles for p = .005, 0.01 0.025, 0.05 (i.e. the lower 0.5%, 1%, 2.5% and 5% points of F) as shown in example below.

Example. To find $F_p(v_1, v_2)$ for $v_1 = 4$, $v_2 = 8$, p = 0.05.

The required fractile is 1/6.04 = 0.166, the value 6.04 being the upper 5% point of F with $v_1 = 8$ and $v_2 = 4$ d.f.

b. Interpolation in Table 6.1 (v_1 -and v_2 -wise)

In Table 6.1, the larger values of v_1 and v_2 have been chosen to be in harmonic progression. This is because, for large values of v_1 and v_2 , quadratic or even linear interpolation, with the reciprocal of the d.f. as the argument, is sufficiently accurate.

Formulae for harmonic interpolation

_	ví—wise	linear	v ₁ —wise	quadratic
	9 < v ₁ < 12	$(1-u^*)y_3+u^*y_{12}$	10 < v₁ ≤ 16	$\frac{u(u+1)}{2} y_3 - (u^2-1)y_{12} + \frac{u(u-1)}{2} y_{24}$
.;··	12< v _i < 24	$(1-u^*)y_{12}+u^*y_{24}$	v ₁ ≥ 17	$\frac{u(u+1)}{2}y_{12} - (u^2 - 1)y_{24} + \frac{u(u-1)}{2}y_{\infty}$
	v ₁ > 24	$(1-u^*)y_{24}+u^*y_{\infty}$		

v ₂ —wise	linear	v ₂ — wise	quadratic
$30 < v_2 < 40$	$(1-u^*)y_{30}+u^*y_{40}$	31 < v ₂ < 34	$\frac{u(u+1)}{2}y_{24} - (u^2 - 1)y_{30} + \frac{u(u-1)}{2}y_{40}$
$40<\nu_2<60$	$(1-u^*)y_{10}+u^*y_{60}$	35 < v ₂ ≤ 48	$\frac{u(u+1)}{2}y_{30} - (u^2-1)y_{40} + \frac{u(u-1)}{2}y_{60}$
$60 < v_2 < 120$	$(1-u^*)y_{60}+u^*y_{120}$	49 ≤ v ₂ ≤ 80	$\frac{u(u+1)}{2}y_{40} - (u^2-1)y_{60} + \frac{u(u-1)}{2}y_{12}$
		81 ≤ v ₂ ≤ 119	$\left \frac{u(u+1)}{2} y_{00} - (u^2-1) y_{120} + \frac{u(u-1)}{2} y_{\infty} \right $

Note: (1) $u^*=u$ if $u \ge 0,=1+u$ if u < 0

⁽e) y_k is the tabulated value for $v_1 = k$ in the formulae for v_2 —wise interpolation and for $v_2 = k$ in the formulae for v_2 wise interpolation

40	0	55	0.1818	70	-0.2857	85	0.4118	100	0.2000	115	0.0435
41.	-0.0732	56	0.1429	71	-0.3099	86	0.3953	101	0.1881	116	0.0345
42	-0.1429	57	0.1053	72	-0.3333	87	0.3793	102	0.1765	.117	0.0256
43	-0.2092	58	0.0690	73	-0.3562	88	0.3636	103	0.1650	118	0.0169
44	-0.2727	59	0.0339	74	-0.3784	89	0.3483	104	0.1538	119	0.0084

Example. To compute $F_p(v_1, v_2)$ for $v_1 = 6$, $v_2 = 44$, p = 0.95.

A v_2 -wise interpolation is necessary. For $v_2=44$, we have u=-0.2727, and $u^*=1+u=.7273$. Also from Table 6.1 we have $y_{40}=2.34$ and $y_{60}=2.25$. Hence the required value

$$y_{44} = (1+u^*)y_{40} + u^*y_{60} = 2.315.$$

For higher accuracy the Cornish-Fisher expansion of z_p (the *p*-th fractile of $z = \frac{1}{2} \log_e F$) may be used.

$$\begin{split} z_p &= x \, \sqrt{\left(\frac{\sigma}{2}\right)} - \delta \, \left(\frac{x^2 + 2}{6}\right) + \sqrt{\left(\frac{\sigma}{2}\right)} \Big\{ \sigma \Big(\frac{x^3 + 3x}{24}\Big) + \frac{\delta^2}{\sigma} \Big(\frac{x^3 + 11x}{72}\Big) \Big\} \\ &- \Big\{ \delta \sigma \Big(\frac{x^4 + 9x^2 + 8}{120}\Big) - \frac{\delta^3}{\sigma} \Big(\frac{3x^4 + 7x^2 - 16}{3240}\Big) \Big\} + \sqrt{\left(\frac{\sigma}{2}\right)} \Big\{ \sigma^2 \left(\frac{x^5 + 20x^3 + 15x}{1920}\right) \\ &+ \delta^2 \left(\frac{x^5 + 44x^3 + 183x}{2880}\right) + \frac{\delta^4}{\sigma^2} \left(\frac{9x^5 - 284x^3 - 1513x}{155520}\right) \Big\} \\ &+ \Big\{ \delta \sigma^2 \Big(\frac{4x^6 - 25x^4 - 177x^2 + 192}{20160}\Big) + \delta^3 \Big(\frac{4x^6 + 101x^4 + 117x^2 - 480}{90720}\Big) \\ &- \frac{\delta^5}{\sigma^2} \Big(\frac{12x^3 + 513x^4 + 841x^2 - 2560}{1632960}\Big) \Big\} + \dots \dots \end{split}$$

where x is the p-th fractile of the standard normal distribution,

$$\sigma=\frac{1}{\nu_1}+\frac{1}{\nu_2},\quad \delta=\frac{1}{\nu_1}-\frac{1}{\nu_2}$$

The coefficients in the expansion are given below for selected values of p.

Sufficient digits have been retained so as to ensure accuracy in the sixth place of decimal for $v_1 > 24$ and $v_2 > 60$,

c. Applications

Some uses of Table 6.1 are illustrated in the following examples.

(i) Ratio of Variances-tests and confidence intervals

Example. Use the data given in subsection c of chapter 4 to test if the two-lots reveal equal variability in respect of impact strength. Denoting the variances of impact strength in lots 1 and 2 by σ_1^2 and σ_2^2 respectively, the problem reduces to testing $\theta = \sigma_1^2/\sigma_2^2 = 1$. To test against alternatives $\sigma_1^2 \neq \sigma_2^2$ compute F by putting the larger mean square in the numerator and compare it with the upper 2.5% value of F with the corresponding degrees of freedom. Thus F = .087/.079 = 1.101. The upper 2.5% value of F (with $\nu_1 = 7$ and $\nu_2 = 9$) is 4.20. Hence the hypothesis $\theta = 1$ cannot be rejected on the basis of the given data.

One can make 95% confidence statements of the following kind.

- (a) σ_1^2/σ_2^2 does not exceed $s_1^2/s_2^2 \div 0.27 = 4.08$
- (b) σ_1^2/σ_2^2 is not less than $s_1^2/s_2^2 \div 3.29 = 0.33$
- (c) σ_1^2/σ_2^2 lies between $s_1^2/s_2^2 \div 4.20 = 0.26$ and $s_1^2/s_2^2 \div 0.21 = 5.24$.

where 0.27 and 3.29 are respectively the lower and upper 5% points, and 0.21 and 4.20 the lower and upper 2.5% points of F with $\nu_1 = 7$ and $\nu_2 = 9$.

(ii) Analysis of variance—one-way classification

Example. Five sets of six mixes, each mix providing 24 doughnuts, were cooked in five types of fats. The table below gives in grams the fat absorbed per mix. Test if the amount of fat absorbed is a characteristic of the type of fat used for cooking.

GRAMS OF FAT ABSORBED BY MIX OF 24 DOUGHNUTS

				
		type of fat		
1	2.	3	. 4 :	5
24	33	37	38	23
32	21	43	51	25
28	50	57	57	4
37	40	29	42	37
16	57	39	45	25
55	27	47	37	36
192	228	252	270	150
	32 28 37 16 55	32 21 28 50 37 40 16 57 55 27	24 33 37 32 21 43 28 50 57 37 40 29 16 57 39 55 27 47	1 2 3 4 24 33 37 38 32 21 43 51 28 50 57 57 37 40 29 42 16 57 39 45 55 27 47 37

Grand total G = 1092. Total number of observations, n = 30.

Correction factor (C.F.) =
$$G^2/n = G^2/30 = 39748.8$$

$$Total S.S. = 24^2 + 32^2 + 28^2 + ... + 25^2 + 36^2 - C.F. = 44592.0 - 39748.8 = 4843.2$$

S.S. due to fats
$$=\frac{T_1^2}{n_1} + \frac{T_2^2}{n_2} + \ldots + \frac{T_k^2}{n_k}$$
 C.F. (where T_i is the total for the *i*-th fat with

 n_i observations)

$$= \frac{1}{6} (192^2 + 228^2 + \dots + 150^2) - \text{C.F.} = 41292.0 - 39748.8 = 1543.2.$$

ANALYSIS OF VARIANCE TABLE

sources of variation	d.f.	ş.s.	m.s.	F = ratio of m.s.
between fats	- 4	1543.2	385.8	2.922*
within fats	25	3300.0†	132.0	
total	29	4843.2		

† obtained by subtraction.

The upper 5% and 1% values of F (for $v_1 = 4$, $v_2 = 25$) are 2.76 and 4.18 respectively. The results are thus significant at the 5% level and it may be concluded that the amount of fat absorption depends on the fat used for cooking.

(iii) Multiple correlation—test of significance

The multiple correlation coefficient between rate of gain in weight (x_1) and two other variables, initial weight (x_2) and age (x_3) , was $R_{1\cdot 23}=0.421$, based on observations on 40 swines.

To test for its significance, compute

$$\frac{n-k-1}{k} \quad \frac{R^2}{1-R^2} = \frac{37}{2} \quad \frac{(0.421)^2}{1-(0.421)^2} = 3.991$$

where k is the number of independent variables, and n is the sample size.

The upper 5% and 1% values of F (with $v_1 = k = 2$ and $v_2 = n - k - 1 = 37$) are 3.25 and 5.23 respectively (values obtained by interpolation). Hence the observed values of $R_{1,23}$ is significant at the 5% level (though not at the 1% level).

(iv) Test of mean values in multivariate normal populations

Example. Differences d_1 and d_2 in head length and head breadth between first-born and second-born sons were observed on 25 families. Test if the first-born in a family differs significantly from the second-born, in respect of these two characteristics.

The following values were obtained from the data

Mean difference:
$$\bar{d}_1 = 1.88$$
, $\bar{d}_2 = 1.48$.

The dispersion matrix of the differences estimated on 24 d.f. (obtained by dividing the corrected sum of squares and products by 24) is given by

$$w_{11} = 68.03, \ w_{12} = 11.52, \ w_{33} = 24.01$$

The inverse of this matrix is,

$$w^{11} = 0.0159999$$
, $w^{12} = -0.007677$, $w^{22} = 0.045332$.

The problem is equivalent to testing if the sample mean vector (\bar{d}_1, \bar{d}_2) differs significantly from (0, 0). The appropriate statistic (which is distributed as F on k and n-k d.f.) is

$$\frac{n-k}{(n-1)k} \left[n\Sigma \ \Sigma w^{ij} \ \bar{d}_i \ \bar{d}_j \ \right] = \frac{23}{2} \cdot \frac{25}{24} \ (0.113121) = 1.3548.$$

where n is the sample size and k is the number of variables. Note that $n(w^{ij})$ is the inverse of the estimated dispersion matrix of \bar{d}_1 and \bar{d}_2 . The upper 5% value of F (with $v_1 = k = 2$ and $v_2 = n - k = 23$) = 3.42. Since 1.3548 is less than this value, it is concluded that the data do not provide evidence of differences in the dimensions of the firstborn and second-born sons.

d. Another table

MERRINGTON, M. and THOMPSON, C. M. (1943): Tables of percentage points of the inverted beta (F) distribution, Biometrika, 33, 73-88.

Gives to 5 figures fractiles of the F distribution for the following values of p_{ν_1} , and ν_2 .

p = 0.50, 0.75, 0.90, 0.95, 0.975, 0.99, 0.995.

 $v_1 = 1(1)10$, 12, 15, 20, 24, 30, 40, 60, 120, ∞

 $v_2 = 1(1)30, 40, 60, 120, \infty$

6.2. BETA FUNCTION REPRESENTATION

a. Introduction

Table 6.2 gives upper 1% and 5% values of the beta distribuion with the density

$$\frac{1}{B(a,b)}\ u^{a-1}(1-u)^{b-1}, 0\leqslant u\leqslant 1,$$

for the following values of the parameters α and b:

$$2a = 1(1) 9, 12, 24, \infty$$

 $2b = 1(1)30, 40, 60, 120, \infty.$

Fractiles corresponding to p = 0.01, 0.05 (the lower 1% and 5% points) can be read from Table 6.2 by interchanging a and b and taking the difference from unity of the table entry.

Example. To find the fractile for 2a = 5, 2b = 7, and p = 0.05. The required fractile is 1-0.87222 = 0.12778, 0.87222 being the upper 5% point (0.95th fractile) of beta with 2a = 7, 2b = 5.

b. Beta distribution—its relation to the distribution of the variance ratio (F) and the null-distribution of the multiple correlation coefficient

Consider the two transformations

$$(1) \quad u = \frac{\mathsf{v}_1 F}{\mathsf{v}_2 + \mathsf{v}_1 F}$$

(2)
$$u = \frac{v_2}{v_2 + v_1 F}$$
.

The first equation transforms the variance ratio (F) having parameters v_1 and v_2 (d.f. of numerator and denominator) to a beta variable having parameters $a = \frac{v_1}{2}$, $b = \frac{v_2}{2}$ while the second transforms the same variance ratio to a beta variable with parameters a and b interchanged i.e.: $a = \frac{v_2}{2}$, $b = \frac{v_1}{2}$. Table 6.2 directly gives the significant values of R^2 the square of the multiple correlation coefficient with 2a = k, the number of independent variables and 2b = n - k - 1, where n is the sample size. In 6.1c the significance of R^2 was judged by first computing a function of R^2 which is distributed as F and referring to the F table.

c. The incomplete beta function—its relation to cumulated binomial probabilities

An equation connecting the incomplete beta integral with the cumulative sum of binomial probabilities is given in 1.3b. The use of Table 6.2 in determining one-sided confidence limits to the parameter π of the binomial distribution and in providing one sided tests of hypothesis concerning π is already demonstrated in 1.3b and c.

TABLE 6.2. THE BETA DISTRIBUTION (Upper 1% values)

N

The table gives the values of α for which $\int u^{\alpha-1}(1-u)^{b-1}du/B(a,b) = 0.05$

6.3. The Distribution of s_{max}^2/s_{min}^2

a. Introduction

Table 6.3 gives the upper 1% and 5% values of $s_{\text{max}}^2/s_{\text{min}}^2$ where s_{max}^2 and s_{min}^2 are respectively the largest and the smallest in a set of k independent mean squares each based on ν d.f.

b. Application

Seven pieces of yarn were sampled from each of 5 spinning frames and tested for tensile strength. The values of s^2 for the 5 frames are 0.0297, 0.0429, 0.0381, 0.1181, 0.0467. To test whether the variability is the same for all frames, compute: $s_{\text{max}}^2/s_{\text{min}}^2 = 0.1181/0.0297 = 3.98$. The 5% value of $s_{\text{max}}^2/s_{\text{min}}^2$ for k = 5 and $\nu = 6$ is 12.1, so that the observed ratio is not significant at the 5% level.

(Upper 1% points)

TABLE 6.3. UPPER PERCENTAGE POINTS OF $s_{\text{max}}^{\ 2}/s_{\text{min}}^{\ 2}$

Values in the column k=2 and in the rows $\nu=2$ and ∞ are exact. Elsewhere the third-digit may be in error by a few units for the 5% points and several units for the 1% points. The third digit figures in brackets for $\nu=3$ are the most uncertain.

7. THE CORRELATION COEFFICIENT

In 4c was described a t test for testing the significance of an observed sample correlation coefficient. Table 7.1 gives directly the significant values of r (the sample total or partial correlation coefficient under the assumption of normality) correct to three places of decimal and d.f. = 1(1) 30 (10) 80, 100(50) 300. With this table, the computation of t for testing the significance of r, is unnecessary.

The first three columns give 5%, 1% and 0.1% level values of |r| for two sided tests. The next three columns give upper tail values for one sided tests at 5%, 1% and 0.1% levels of significance. A negative sign prefixed to these upper tail critical values provides the corresponding lower tail values.

Example: The value of the sample correlation coefficient between head length and head breadth computed from measurements on 30 individuals is 0.415. To test the hypothesis that the population correlation coefficient is zero.

Here the d.f. is 30-2=28 and the 5% tabulated value for 28 d.f. is 0.361 for a two sided test. The observed value being larger, the result is significant at the 5% level. If it is known apriori that under the alternative hypothesis the population correlation coefficient would be positive, a one sided test is used for judging the significance of the observed correlation coefficient. The 5% tabulated value for one sided test is 0.306, thus establishing significance of the observed correlation coefficient.

TABLE 7.1 THE CRITICAL VALUES OF THE CORRELATION COEFFICIENT (TOTAL OR PARTIAL)

	two	-sided		one-sided			twosided					onersided

5%, 1% and 0.1% values for one-sided (upper tail) and two-sided tests

Note that for testing the significance of correlation coefficient (total) computed form n pairs of observations, the appropriate degrees of freedom are n-2. For testing the significance of a partial correlation coefficient between two variables eliminating k independent variables, computed from observations on n individuals (i.e. on n sets of observations) the degrees of freedom are n-2-k. Thus the partial correlation coefficient $r_{12.3456} = 0.63$ based on 30 observations is significant against the 5% critical value on 24 d.f.

8. TRANSFORMATIONS

8.1. The Sin-1 \sqrt{p} Transformation For The Binomial Proportion

Introduction

Table 8.1 gives the values of $\sin^{-1}\sqrt{p}$ (in degrees, correct to 3 places of decimal) for p = 0.000(0.001)0.200 (0.005)0.500. For $0.500 , use the formula <math>\sin^{-1}\sqrt{p} = 90 - \sin^{-1}\sqrt{1-p}$. Thus

$$\sin^{-1}\sqrt{0.785} = 90 - \sin^{-1}\sqrt{0.215} = 90 - 27.625 = 62.375.$$

b. Interpolation in Table 8.1.

For interpolation within the interval 0.000 to 0.030 use the formula $\sin^{-1}\sqrt{p} = 57.29578\sqrt{p}(1+p/6)$ degrees. Linear interpolation should suffice in the interval (0.030-0.500). To facilitate linear interpolation within the interval 0.200 to 0.500, values of $\Delta'(=200\Delta)$ have also been provided in an adjacent column, the formula applicable being

$$\sin^{-1}\!\sqrt{p}=\sin^{-1}\!\sqrt{p_0}\!\!+\!\Delta'(p\!-\!p_0)$$

where p_0 is the nearest tabular argument below p. Thus

 $\sin^{-1}\sqrt{0.3035} = \sin^{-1}\sqrt{0.300} + \Delta'(0.0035) = 33.211 + 62.4(0.0035) = 33.429$ observing that the tabulated value of Δ' for p = 0.300 is 62.4

c. Application

The binomial proportion x/n has mean π and standard deviation $[\pi(1-\pi)/n]^{t}$, but the standard error of $\sin^{-1}\sqrt{p}$ (expressed in degrees as in Table 8.1) is independent of π and is equal to $28.64789/\sqrt{n}$ degrees. Because of this there is some theoretical advantage in transforming an observed proportion p to $\sin^{-1}\sqrt{p}$ in the comparison of proportions in one or multiple way classification by analysis of variance.

The table is also useful in evaluating the inverse of other trigonometric functions. $\cos^{-1}x = \sin^{-1}\sqrt{1-x^2}$, $\csc^{-1}x = \sin^{-1}(1/x)$,

$$\tan^{-1}x = \sin^{-1}\sqrt{x^2/(1+x^2)}, \quad \sec^{-1}x = \sin^{-1}\sqrt{(x^2-1)/x^2},$$

$$\cot^{-1}x = \sin^{-1}\sqrt{1/(1+x^2)}$$
.

Thus $\tan^{-1}1.24 = \sin^{-1}\sqrt{0.6059} = 90 - \sin^{-1}\sqrt{1 - 0.6059} = 90 - \sin^{-1}\sqrt{0.3941}$.

$$= 90 - 38.886 = 51.114$$

using the table to find $\sin^{-1}\sqrt{0.3941}$.

d. Some other tables

- 1. SNEDECOR, G. W. (1946): Statistical Methods, 4th Ed., Iowa State Univ. Press, Ames, Iowa, gives Sin-1 \sqrt{p} correct to two places of decimal for p = 0(0.0001) .01(.001) .99(.0001)1.
- Fisher, R. A. and Yates, F. (1957): Statistical Tables for Biological, Agricultural and Medical Research, 5th edition, Oliver and Boyd, London,

gives $\sin^{-1}\sqrt{p}$ correct to one place of decimal for p=0(0.01) 0.99 (Table X) and also for p=x/n; x=1(1) [$\frac{1}{2}n$], n=2(1) 30 (Table XI).

3. Hald, A. (1952): Statistical Tables and Formulas, John Wiley and Sons, New York.

Table 12 gives $2 \sin^{-1} \sqrt{p}$ in radians, correct to four places of decimal for p = 0(0.001) 1.000.

Interpolation in Table 8.1

For p < 0.03, use the formula $\sin^{-1}\sqrt{p} = 57.29578(1+p/6)\sqrt{p}$. Linear interpolation would suffice elsewhere. For $0.03 if <math>p_0$ and p_1 be two consecutive arguments in the first table such that $p_0 , use the formula <math>\sin^{-1}\sqrt{p} = 10^3[(p_1-p)\sin^{-1}\sqrt{p_1}+(p-p_0)\sin^{-1}\sqrt{p_0}]$. For p > 0.20 the values of Δ' given in Table 8.1 could be used in the following formula for linear interpolation

$$\sin^{-1}\sqrt{p} = \sin^{-1}\sqrt{p_0} + \Delta'(p-p_0)$$

where p_0 is the nearest tabular argument below p. For p > .500, use the formula $\sin^{-1} \sqrt{p} = 90 - \sin^{-1} \sqrt{1-p}$.

8.2. THE TANH-1 TRANSFORMATION FOR CORRELATION COEFFICIENT

a. Introduction

Table 8.2 gives the values of $z = \tanh^{-1}r = \frac{1}{2}\log_e \frac{1+r}{1-r}$ correct to five places of decimal for $r = 0.00(0.02) \ 0.20(0.002) \ 0.860(0.001) \ 0.999$.

b. Interpolation in Table 8.2

Within the interval 0.20 < r < 0.95, linear interpolation gives accuracy to four places of decimal For 0 < r < 0.20 the formula

$$\tanh^{-1}r = r + \frac{r^3}{3}$$

could be used. For $0.95 < r \le 0.99$ quadratic interpolation is necessary to achieve the same degree of accuracy. Interpolation in the table is not advisable for values of r > 0.99. In such a case one should compute $\tanh^{-1}r$ directly using the formula

$$z = \tanh^{-1}r = \frac{1}{2}\log_e \frac{1+r}{1-r}.$$

c. Application

(i) The product moment correlation coefficient (interclass correlation)

For the sample correlation coefficient r in a sample of size n from the bivariate normal population,

$$E(r) = \rho \left[1 - \frac{1}{2n} - \frac{3}{8n^2} + \rho^2 \left(\frac{1}{2n} - \frac{3}{4n^2} \right) + \rho^4 \frac{9}{8n^2} \right] + \dots$$

$$\sim \rho \left[1 - \frac{1 - \rho^2}{2(n-1)} \left\{ 1 - \frac{1}{4(n-1)} \left(1 - 9\rho^2 \right) \right\} \right]$$

and variance

$$V(r) = \frac{1}{n} (1 - \rho^2)^2 \left(1 + \frac{1}{n} + \frac{11\rho^2}{2n} \right) + \dots$$

$$\sim \left[\frac{1 - \rho^2}{\sqrt{n - 1}} \left\{ 1 + \frac{11\rho^2}{4(n - 1)} \right\} \right]^2$$

where ρ is the population coefficient. For large n,

$$\zeta = E(z) = \tanh^{-1}\rho + \frac{\rho}{2(n-1)} + \dots \sim \tanh^{-1}\rho$$

$$V(z) \sim \frac{1}{n-3}.$$

and

The same formulae for expectation and variance hold good for a partial correlation coefficient with n changed to n-p where p is the number of variables eliminated.

d. The intraclass correlation coefficient

For the intraclass correlation coefficient r, based on k variates within a class, Fisher proposed the transformation $z = \frac{1}{2} \log_{\epsilon} \frac{1 + (k-1)r}{1-r}$ The transformed value in this case may be obtained by first computing $r' = \frac{kr}{2 + (k-2)r}$ and reading the value of $\tanh^{-1} r'$ from Table 8.2.

For a given value of $\frac{1}{2}\log_e\frac{1+(k-1)r}{1-r}=c$ the corresponding value of r may be obtained in a similar manner by first obtaining the value of r'= tanh c by inverse interpolation in Table 8.2 and computing

$$r = \frac{2r'}{2r' + k(1-r')}$$

The expected value and variance of z, in sampling from a normal population, are given by

$$E(z) \sim \frac{1}{2} \log_e \frac{1 + (k-1)\rho}{1 - \rho}$$

$$V(z) \sim k/2(k-1)(n-2)$$

The transformation to z would be useful in testing for an assigned value of the correlation coefficient (total, partial or intra-class) or in testing the equality of k correlation coefficients on the basis of estimates.

e. Another table

HARVARD UNIVERSITY COMPUTATION LABORATORY (1949): Tables of Inverse Hyperbolic Functions, The Annals of the Computation Laboratory of Harvard University, 20, Harvard Univ. Press, Cambridge (Massachusetts)

gives $\tanh^{-1} x$ to 9 places of decimal for x = 0(0.001) 0.5 (0.0005) 0.75 (0.0002) 0.9 (0.0001) 0.95 (0.00005) 0.975 (0.00002) 0.99 (0.00001) 0.99999.

9. ORDER STATISTICS

9.1. EXPROTED VALUES OF ORDER STATISTICS

a. Introduction

Consider a sample $(x_1, x_2, ..., x_n)$ of size n from a standard normal distribution. Let these observations be arranged in increasing order of magnitude as follows

$$x_{(1)}\leqslant x_{(2)}\leqslant\ldots\leqslant x_{(n)}.$$

Table 9.1 provides the expected value of $x_{(i)}$ given by

$$Ex_{(i)} = \int_{-\infty}^{\infty} \frac{n!}{(i-1)!(n-i)} x \left[\int_{-\infty}^{x} N(w)dw \right]^{i-1} \left[\int_{x}^{\infty} N(w)dw \right]^{n-i} N(x)dx$$

for i = [(n+1)/2] (1) n, n = 2(1)30. For i < [(n+1)/2] the expected values are obtained using the relation

$$Ex_{(i)} = -Ex_{(n-i+1)}.$$

b. Applications

Table 9.1 is useful in the analysis of ordinal data where one has to replace the ranks by the expected values of the corresponding normal order statistics. Here the next step often involves an analysis of variance of these assigned scores. The sums of squares of the expected values given in Table 9.1 are useful in these calculations. See also the explanatory notes preceding Table 10.3 in this connection.

Another use of Table 9.1 is in obtaining factors by which the range or a quasirange, in a sample of size n from the normal population $N(\mu, \sigma)$, has to be multiplied to give an estimate of the standard deviation σ . Thus we see from Table 9.1 that in a sample of size 20, $[x_{(18)}-x_{(3)}] \div 2.26$ provides an unbiased estimate of the population standard deviation, since for n=20, $Ex_{(18)}=Ex_{(n-2)}=1.13\sigma$ and $Ex_{(3)}=-Ex_{(n-3+1)}=-1.13\sigma$.

c. Another table of expected values

HARTER, H. L. (1960): Expected values of Normal Order Statistics, Technical report 60-292, Aeronautical Research Laboratories, Wright-Patterson Air Force Base, June 1960.

Expected values to five places of decimal for n=2(1)100 and for selected values upto n=400.

9.2. Fractiles of a Normal Distribution

a. Fractile mean and variance

For a standard normal distribution with the density function $N(x) = (2\pi)^{-\frac{1}{2}}$ $e^{-x^2/2}(-\infty < x < \infty)$, consider the system of intervals $(a_i, a_{i+1}]$ i = 1, 2, ..., g where $a_1 = -\infty$, $a_{g+1} = \infty$ and the g-1 other a's are chosen such that

$$\int_{a_i}^{a_{i+1}} N(x)dx = \frac{1}{g} \quad (i = 1, 2, ..., g).$$

The interval $(a_i, a_{i+1}]$ will be referred to as the *i*-th *g*-fractile interval of the standard normal distribution. Table 9.2 gives the mean

$$\mu_{[i,\,\theta]} = g \int\limits_{a_i}^{a_{i+1}} x N(x) dx$$

and variance.

$$\sigma_{[i,g]}^2 = g \int_{a_s}^{a_{i+1}} x^2 N(x) dx - \mu_{[i,g]}^2$$

in the *i*-th g-fractile-interval for i = 1(1)g, g = 2(1)20

b. Application: graphical tests of normality

Let $x_1, x_2, ..., x_n$ be a sample of *n* observations from a population. Two graphical tests are described for examining whether the parent population is normal.

(i) Normal probability graph

Denote the ordered observations by $x_{(1)}$, $x_{(2)}$, ..., $x_{(n)}$. Consider the pairs $(d_1, x_{(1)})$, ..., $(d_{n-1}, x_{(n-1)})$ where d_i is the standard normal deviate corresponding to the cumulative probability of i/n. The values of d_i can be obtained from Table 3.1, by inverse interpolation if necessary. Then the $(d_i, x_{(i)})$, i = 1, 2, ..., (n-1) are plotted on a graph paper with orthogonal axes (x and y) with d_i on x-axis and $x_{(i)}$ on y-axis. If the parent population is normal the points will lie close to a straight line.

(ii) Fractile graph*

We consider the order observations $x_{(1)}, x_{(2)}, ..., x_{(n)}$ as in method I. Now divide the observations into a chosen number, g, of groups such that each group consists of h = n/g consecutive order observations. The groups so obtained are called fractile groups. The *i*-th fractile group consists of the observations

$$x_{(ih)}, x_{(ih+1)}, \ldots, x_{(ih+h-1)}$$

The sample *i*-th fractile mean is the average of the observations in the *i*-th fractile group and is represented by

$$\overline{x}_{[i \ \rho]} = \frac{x_{(ih)} + \ldots + x_{(ih+h-1)}}{h}$$

^{*} The fractile graphical analysis was recently developed by Mahalanobis (Econometrica, 28, 325 351). It is capable of a very wide application. The particular application of testing for normality was suggested by A. Linder in the convocation address at the Indian Statistical Institute in 1963.

We consider the pairs

$$(\mu_{[i,g]}, x_{[i,g]}), i = 1, 2, ..., g$$

where $\mu_{[i,g]}$ are the fractile means of the population as defined in section 1, and tabulated in Table 9.2. Then the g points $(\mu_{[i,g]}, x_{[i,g]})$, i = 1, 2, ..., g are plotted on a two dimensional chart representing $\mu_{[i,g]}$ on x-axis and $x_{[i,g]}$ on y-axis. If the parent population is normal the graph will be close to a straight line.

Example: Given 100 independent observations on log weight of an individual, it is required to examine whether the distribution of log weight is normal.

We illustrate the fractile graph method which is less well-known than the probability graph method.

In such problems involving graphical analysis of data, it is useful to split the sample into two independent half samples (of 50 observations each in the present case) and draw the fractile graph for each half sample and also for the combined sample. Such a procedure would enable us to examine the consistency between parallel samples and also to have an idea of the magnitude of the sampling error (separation between half sample graphs) involved. The observed deviation from a traight line of the fractile graph for the combined sample has to be judged against sampling error, i.e., the deviation to be expected due to sampling.

	fractile mean		le mean			
fractile group	half s	sample 2	combined sample	theoretical (from Table 9.2)		
4.11	2.076	2.060	2.068	-1,755		
2	2.096	2.102	2.097	-1.045		
3	2.108	2.125	2.117	-0.677		
4	2.126	2.134	2.131	-0.387		
5	2.150	2.139	2,143	-0.126		
6	2.169	2.154	2.162	0.126		
7	2.175	2.171	2.174	0.387		
8	2.186	2.194	2.190	0.677		
9	2.204	2.222	2.211	1.045		
10	2.247	2.254	2.253	1.755		

The two fractile graphs based on samples of 100 observations are in the chart on page 94. The deviations from a straight line appear to be small compared to the difference between the half sample fractile graphs.

TABLE 9.2. MEAN AND VARIANCE FOR FRACTILES OF A STANDARD NORMAL DISTRIBUTION

For each combination of a value of g and a fractile number there are two entries, of which the top entry represents the mean and the lower entry, the variance

9.3. THE MAXIMUM OBSERVATION

Table 9.3 provides the upper 5%, 1% and 0.1% points of the maximum observation $x_{(n)}$ in a sample of size n from N(0, 1) for n = 1 (1)30. Owing to the symmetry of N(0, 1) the same table is also applicable to $-x_{(1)}$, $x_{(1)}$ being the minimum observation in a sample of size n.

It is known from experience that the average and standard deviation of the weight of individual cigarettes are 6.00 and 1.50 units. 5 cigarettes selected at random weighed 6.00, 9.50, 4.41, 7.51 and 4.29 units. Examine if the maximum observation is an outlier The extreme standardised deviate (9.50-6.00)/1.50=2.33. This exceeds 2.319 the upper 5% value given in Table 9.3 for n=5. Hence one has reasons to suspect the maximum observation.

9.4. THE EXTREME STUDENTISED DEVIATE FROM THE SAMPLE MEAN

Table 9.4 gives the upper 1% and 5% points of $\frac{x_{(n)}-\bar{x}}{s_{\nu}}\left(\text{or }\frac{\bar{x}-x_{(1)}}{s_{\nu}}\right)$ computed from a sample of size n drawn from $N(\mu,\sigma)$, where \bar{x} is the sample mean $x_{(1)}$ and $x_{(n)}$ are the minimum and the maximum observation in the sample and s_{ν}^2 is an independent unbiased estimate for σ^2 based on ν degree of freedom.

Table 9.4 is useful in deciding whether to reject an allegedly outlying observation, as in 9.3 when the population mean and variance are unknown.

9.5. W TEST FOR NORMALITY

a. Introduction

Of all the known tests for normality, the W test given by Shapiro and Wilk (Biometrika 52, 1965) is generally efficient against a wide spectrum of non-normal alternatives, and can be effective even when the sample size is small. Given n observations $x_1, x_2, ..., x_n$, the W statistic is computed as follows:

- (i) Rearrange the observations to obtain the ordered sample $x_{(1)}, x_{(2)}, \ldots, x_{(n)}$
- (ii) Compute $\bar{x} = (\Sigma x)/n$ and $S^2 = \Sigma x_i^2 n\bar{x}^2$.
- (iii) Compute

$$b = \sum_{i=1}^{k} a_{n-i+1} [x_{(n-i+1)} - x_{(i)}]$$

where k=n/2 if n is even and k=(n-1)/2 if n is odd. The values of a_{n-1+1} are given in Table 9.5 for n=3(1)50 and i=1 to $\frac{n}{2}$ (or $\frac{n-1}{2}$)

(iv) Then compute $W = b^2/S^2$.

The hypothesis of normality is rejected at p% level if $W \leq W_p$. The critical values of W_p are given in Table 9.6 for p=1, 2, 5, 10, 50 and n=3(1)50. (Note that the exact distribution of W is not known and the percentage points are obtained by simulation and appropriate smoothing).

b. Example

Ten observations on weights of cigarettes (in coded units) after ordering are as follows:

$$x_{(1)} = 303, \ x_{(2)} = 338, \ x_{(3)} = 406, \ x_{(4)} = 457, \ x_{(5)} = 461$$

 $x_{(6)} = 469, \ x_{(7)} = 474, \ x_{(8)} = 489, \ x_{(9)} = 515, \ x_{(10)} = 583$
 $\bar{x} = 449.5, \ S^2 = 60628.$

The value of k = 5, since n = 10. From table 9.5 we have

$$a_{10} = 0.5739, \ a_{2} = 0.3291, \ \dots, a_{6} = 0.0399$$

$$b = a_{10}(x_{(10)} - x_{(1)}) + a_{2}(x_{(2)} - x_{(2)}) + \dots + a_{6}(x_{(6)} - x_{(5)})$$

$$= 0.5739(583 - 303) + 0.3291(515 - 338) + \dots + 0.0399(469 - 461)$$

$$= 239.113.$$

$$W = \frac{(239.113)^2}{60628} = 0.943.$$

and the 5% critical value of W = 0.842 from Table 9.6 for n = 10. Hence on the basis of limited available data, there is no reason to reject the hypothesis of normality.

9.6 TESTS FOR OUTLIERS

a. Introduction

Let $x_{(1)}, x_{(2)}, ..., x_{(n)}$ denote a random sample of n observations from a normal population arranged in the ascending order of magnitude. Dixon $(Ann.\ Math.\ Stat...$ 22, 1951) has tabulated the percentage points of the distribution of the ratios of the form $\frac{x_{(n)}-x_{(n-j)}}{x_{(n)}-x_{(i)}}$ for testing whether $x_{(n)}$ is an outlier and of the form $\frac{x_{(j)}-x_{(1)}}{x_{(n-i)}-x_{(1)}}$ for testing whether $x_{(1)}$ is an outlier, for small values of i and j and $n \leq 30$. Table 9.7 gives the upper 5% and 1% points (or equivalently critical values corresponding to $\alpha = 0.05$ and $\alpha = 0.01$) of the following statistics.

$$r_{10} = \frac{x_{(2)} - x_{(1)}}{x_{(n)} - x_{(1)}} \quad \text{or} \quad \frac{x_{(n)} - x_{(n-1)}}{x_{(n)} - x_{(1)}} \quad \text{for} \quad n = 3(1)7$$

$$r_{11} = \frac{x_{(2)} - x_{(1)}}{x_{(n-1)} - x_{(1)}} \quad \text{or} \quad \frac{x_{(n)} - x_{(n-1)}}{x_{(n)} - x_{(2)}} \quad \text{for} \quad n = 8(1)10$$

$$r_{21} = \frac{x_{(3)} - x_{(1)}}{x_{(n-1)} - x_{(1)}} \quad \text{or} \quad \frac{x_{(n)} - x_{(n-2)}}{x_{(n)} - x_{(2)}} \quad \text{for} \quad n = 11(1)13$$

$$r_{22} = \frac{x_{(3)} - x_{(1)}}{x_{(n-2)} - x_{(1)}} \quad \text{or} \quad \frac{x_{(n)} - x_{(n-2)}}{x_{(n)} - x_{(3)}} \quad \text{for} \quad n = 14(1)25$$

b. Application

The main use of this table is to test whether $x_{(1)}$ or $x_{(n)}$ is an outlying observation. When this method is used for testing an extreme mean, the samples from which the means are computed should all have the same size. The recommended procedure is to use r_{10} for n=3 to 7, r_{11} for n=8 to 10, r_{21} for n=11 to 13 and r_{22} for n=14 to 25. For example, when n=8, we calculate $r_{11}=\frac{x_{(2)}-x_{(1)}}{x_{(n-1)}-x_{(1)}}$ for testing a single outlier $x_{(n)}$ at the lower end or $r_{11}=\frac{x_{(n)}-x_{(n-1)}}{x_{(n)}-x_{(2)}}$ for testing a single large outlier $x_{(n)}$.

Example

Chemical analysis results of a certain chemical content for six samples are as follows:

To test whether $x_{(6)} (= 0.600)$ is an outlier we compute

$$r_{10} = \frac{0.600 - 0.564}{0.600 - 0.470} = 0.28.$$

Since this is less than the critical value 0.560 for $\alpha = 0.05$, $x_{(0)}$ may not be judged to be different from the others.

FORMULAE AND TABLES FOR STATISTICAL WORK

9.7 PROBABILITY PLOTTING

a. Introduction

The technique of probability plotting provides a pictorial representation of the data as well as (a) an evaluation of the reasonableness of the assumed probability model, (b) estimates of the percentiles of the distribution and (c) estimates of unknown parameters of the underlying distribution.

Let $x_{(1)}, x_{(2)}, ..., x_{(n)}$ be an ordered sample of size n from a population with probability density function f(x) and cumulative distribution function F(x). Then the expected value of $x_{(1)}$ is

$$E(x_{(i)}) = \frac{n!}{(i-1)! (n-i)!} \int_{-\infty}^{\infty} y [F(y)]^{i-1} [1-F(y)]^{n-i} dF(y) \qquad \dots \quad (1)$$

For example if & is a uniform variate over the interval (0, 1), then

$$E(x_{(i)}) = \frac{i}{n+1}$$
 for $i = 1, 2, ..., n$.

The expected values of ordered observations have been tabulated for many distributions (see Sarhan and Greenberg, Contributions to Order Statistics, John Wiley 1962). For distributions for which $E(x_{(t)})$ cannot be calculated exactly, the following approximation is frequently used.

$$E(x_{(i)}) = F^{-1} \left(\frac{i - c}{n - 2c + 1} \right) \qquad ... (2)$$

where $F^{-1}[(i-c)/(n-2c+1)]$ is the value of x such that $\int_{-\infty}^x f(u)du = (i-c)/(n-2c+1)$.

that is, the [(i-c)/(n-2c+1)]-th fractile of the distribution and c is a number which depends on n and f(x). The ordered observed values when plotted against their expected values would give a straight line passing through the origin with slope unity. The origin and slope of the plot will change if the variable is linearly transformed for plotting convenience, but the plot will remain a straight line.

The construction of specially scaled graph papers has obviated the need for calculating the expected values for many distributions. The graph paper is scaled in such a fashion that the ordered observations can be plotted directly against 100(i-c)/(n-2c+1), without the need of determining $E(x_{(i)})$. The correct value of c depends on f(x) and n but $c = \frac{1}{2}$ can be used for a wide variety of distributions and sample sizes. The following steps are involved in preparing a probability plot for a given set of data.

- (i) Obtain a probability paper designed for the distribution under examination.
- (ii) Rank the observations from smallest to largest i.e., $x_{(1)} \leqslant x_{(2)} \ldots \leqslant x_{(n)}$.
- (iii) Plot $x_{(i)}$ against 100 $(i-\frac{1}{2})/n$ on the probability paper.

If the chosen model is correct, the points should cluster around a line, although there will be some deviations because of random sampling fluctuations. If a straight line 'appears' to fit the data, find the best fitting line using a suitable method. The probability plot for the normal distribution is discussed in Section **b** of 9.2; we shall briefly describe below the probability plots for the Weibull and Type I Extreme value distributions.

b. Weibull distribution

The cumulative probability distribution function for the Weibull distribution is

$$F(x) = 1 - \exp\left[-\left(\frac{x}{\sigma}\right)^{\eta}\right], \ 0 \leqslant x < \infty \ \eta > 0 \ \sigma > 0$$

where σ and η are the scale and shape parameters respectively. We have with logarithms taken to base e,

$$\log \log \frac{1}{1 - F(x)} = \eta \log x - \eta \log \sigma. \qquad ... (3)$$

Thus for a Weibull variate, $\log \log [1 - F(x)]^{-1}$ has a straight line relationship with $\log x$. The axes of the probability paper are scaled so that $100(i-\frac{1}{2})/n$ can be plotted on the ordinate corresponding to $\log \log [1-F(x)]^{-1}$ and the observed values can be plotted on the abscissa corresponding to $\log x$. Equation (3) can be written as

$$W = a + bz ... (4)$$

where

$$W = \log \log [1 - F(x)]^{-1}$$

$$z = \log x$$

$$b = \eta$$

$$a = -\eta \log \sigma$$

The estimates of the Weibull parameters from the probability plot are

$$\hat{\eta} = \hat{b} \qquad \dots (5)$$

$$\hat{\sigma} = \exp(-\hat{a}/\hat{b})$$

where \hat{a} and b are the intercept and slope respectively of the best line fit.

c. Type I Extreme value distribution

The cumulative extreme value distribution function for the largest element is

$$F(x) = \exp \{-e^{-[(x-\mu)/\sigma]}\}, -\infty < x < \infty, -\infty < \mu < \infty, \sigma > 0$$

where μ and σ are location and scale parameters respectively. Thus the reduced variate

$$y = -\log \{-\log F(x)\} = \frac{x-\mu}{\sigma}$$
 ... (6)

will plot as a straight line against observations from the distribution. Extreme value probability paper is so scaled that $[(i-\frac{1}{2}) \ 100/n]$, can be plotted directly against the-values of the ordered observations. Equation (6) can be written as

$$y = a + bx$$

where $b = \frac{1}{\sigma}$ and $a = \frac{-\mu}{\sigma}$. The estimates of the parameters are

$$\hat{\sigma} = \frac{1}{\hat{h}}$$
 and $\hat{\mu} = -\frac{\hat{a}}{\hat{h}}$

where a and b are the intercept and slope respectively to the best line fit.

a. One sample problem.

To test the hypothesis that a given sample $(x_1, x_2, ..., x_n)$ has arisen from a population with a numerically specified distribution function F(x).

The Kolmogorov-Smirnov test (Table 10.1)

Let $F_n(x)$ be the proportion of observations in the sample less than or equal to x. $F_n(x)$ is called the empirical distribution function. Define

$$\begin{split} D^+(n) &= \sup \left\{ F_n(x) - F(x) \right\} \\ D^-(n) &= \sup \left\{ F(x) - F_n(x) \right\} \\ D(n) &= \sup \left| F_n(x) - F(x) \right| = \max \left\{ D^+(n), D^-(n) \right\}. \end{split}$$

The choice of the test criterion depends on the specific departures intended to be detected.

The 1% and 5% critical values of $D^+(n)$, $D^-(n)$ and D(n) are given in Table 10.1 for n=1(1) 20(5)35 in the special case where F(x) is continuous. A computed value of the criterion larger than or equal to the critical value given in Table 10.1 is significant. Table 10.1 also gives formulae for calculating the critical values when n is large.

Example. Test if the observations .068, .098, .117, .136, .317, .628 could have arisen in sampling from a rectangular distribution over the interval (0, 1).

Here n = 6, and D(n) = .531. The 5% value of D(n) for n = 6 is 521. Hence the observed value is significant at the 5% level.

b. Two sample problem

Consider two samples $(x_{11}, x_{12}, ..., x_{1n_1})$ and $(x_{21}, x_{22}, ..., x_{2n_2})$ of size n_1 and n_2 respectively and the hypothesis that both the samples have arisen from the same population.

(i) The Kolmogorov-Smirnov test (Table 10.2)

Let F_{1n_1} and F_{2n_2} be the empirical distribution functions derived from samples 1 and 2 respectively. Define

$$\begin{split} D^+(n_1, \, n_2) &= \sup \left\{ F_{n_1}(x) - F_{n_2}(x) \right\} \\ D^-(n_1, \, n_2) &= \sup \left\{ F_{n_2}(x) - F_{n_1}(x) \right\} \\ D(n_1, \, n_2) &= \sup \left| F_{n_1}(x) - F_{n_2}(x) \right| \\ &= \max \left\{ D^+(n_1, \, n_2), \, D^-(n_1, \, n_2) \right\}. \end{split}$$

The choice of the test criterion depends on the specific departures from the hypothesis intended to be detected.

For the special case $n_1 = n_2 = n$, Table 10.2 provides 5% and 1% critical values for $n D^+(n, n)$ (or $nD^-(n, n)$) and nD(n, n) covering the values of n = 3(1) 30(5) 40. A computed value of $nD^+(n, n)$ or $nD^-(n, n)$ or nD(n, n) is declared to be significant if it exceeds or is equal to the critical value given in Table 10.2.

When n_1 and n_2 are large the following formulae may be used for calculating the critical values of the test criterion:

one-sided tes $D^+(n_1, n_2)$ or		two-sided test statistic $D(n_1, n_2)$				
1%	5%	1%	5%			
$1.52 \left(\frac{n_1+n_2}{n_1n_2}\right)^{\frac{1}{4}}$	$1.22 \left({n_1 + n_2 \atop n_1 n_2} \right)^{\frac{1}{3}}$	$1.63 \left(\frac{n_1 + n_2}{n_1 n_2}\right)^{\frac{1}{4}}$	$1.36 \left(\frac{n_1+n_2}{n_1n_3}\right)^{\frac{1}{4}}$			

The critical values given in Table 10.2 and also the asymptotic formulae given above are applicable only if the population distribution under the hypothesis is known to be continuous.

(ii) Other tests

Let the observations in the combined sample of size $n = n_1 + n_2$ be serially arranged in increasing order of magnitude

$$x_{(1)}\leqslant x_{(2)}\leqslant\ldots\leqslant x_{(n)}.$$

Let $i_1, i_2, ..., i_{n_2}$, $(1 \le i_1 < i_2 < ... < i_{n_2} \le n)$, be the serial orders of observations in sample 2.

A general form of test statistic for testing the hypothesis of equality of distribution functions is

$$a_n(i_1) + a_n(i_2) + \dots + a_n(i_{n_2})$$

where for each n, a_n (i) is a given function defined over the integers i = 1, 2, ... n. The following are well known special cases:

- (a) Fisher-Yates test
 - $a_n(i)$ = expected value of the *i*-th order statistic in a sample of size *n* from N(0, 1). These expected values are given in Table 9.1.
- (b) Wilcoxon (Mann-Whitney) test $a_n(i) = i$.
- (c) Van der Waerden test

$$a_n(i) = \left(\frac{i}{n+1}\right)$$
-th quantile of $N(0, 1)$ defined by the equation

$$\int_{-\infty}^{a_n(i)} N(t)dt = \frac{i}{n+1}.$$

The values of $a_n(i)$ may be obtained by interpolation in Table 3.2.

(a) The Fisher-Yates test (Table 10.3)

Here observations in each sample are replaced by scores defined in the following manner. If a particular observation has rank i in the combined sample of size n, the score replacing this observation is given by the expected value of the i-th order statistic in a sample of size n from N(0, i). Define

 $C_1 = \text{sum of the scores received by the second sample observations.}$ Table 10.3, provides the 1% and 5% critical values of C_1 for a two sided test and also the upper 1% and 5% values of C_1 for a one sided upper tail test. The lower 1% and 5% values are obtained by prefixing a negative sign to the upper 1% and 5% values respectively. Table 10.3 covers the values of n = 6(1)10 where n_1 is the size

of the smaller sample.

For larger values of n one may apply the usual two sample t-test (described in 4) to the scores.

(b) The Wilcoxon (Mann-Whitney) test (Table 10.4)

Define U_{21} as the number of times an observation in the second sample precedes an observation in the first considering all pairs of observations one from each sample. Clearly

$$U_{i1} = n_1 n_2 + \frac{n_2 (n_2 + 1)}{2} - R_2$$

where $R_2 = \text{sum of the ranks assumed by the second sample observations.}$ Define U_{12} in a similar manner and let $U = \min (U_{12}, U_{21})$.

Table 10.4 provides 1% and 5% critical values of U. An observed value equal to or less than the value given in table is declared to be significant. The selection of the statistic U_{12} , U_{21} or U depends upon the type of alternative hypotheses. For instance if it is desired to examine that the variable of the first population is stochastically larger than the second, one uses U_{12} . If the nature of departure to be detected is not specified one uses U Table 10.4 covers values of n_1 and $n_2 = 1(1)20$.

For larger values of n_1 and n_2 , the sampling distribution of U may be assumed to be normal with

mean =
$$n_1 n_2 / 2$$
,
variance = $n_1 n_2 (n_1 + n_2 + 1) / 12$.

(c) The Wald-Wolfowitz run test (Table 10.5)

Consider the serial arrangement of observations in increasing order of magnitude as discussed in (ii) above and replace each observation by 1 or 2 according as it arises from sample 1 or 2. A run is a succession of like symbols (numerals) preceded and followed by none or an unlike symbol (numeral). Let W be the total number of runs (i.e. the total of the number of runs of 1 and the number of runs of 2). W is proposed as a test statistic.

Table 10 5 provides the lower 1% and 5% critical values of W for n_1 , n_2 upto 20.

For larger values of n_1 , n_2 the sampling distribution of W may be assumed to be normal with

$$\begin{aligned} \text{mean} &= \frac{2n_1n_2}{n_1 + n_2} + 1, \\ \text{variance} &= \frac{2n_1n_2(2n_1n_2 - n_1 - n_2)}{(n_1 + n_2)^2(n_1 + n_2 - 1)}. \end{aligned}$$

Example: In a certain feeding experiment 6 pigs were kept under a control diet while 6 others were provided with feed 'A' The gains in weight (in lbs) over a certain period were as follows:

Examine if feed 'A' is an improvement over 'control'.

Kolmogorov-Smirnov test: Here $5D^+(5,5)=4$ which is equal to the 5% value given in Table 10.2. Hence the hypothesis that the two feeds are equally good is rejected (at the 5% level) in favour of 'A'.

Fisher-Yates test: We get the following rankings for the combined sample of 10 observations:

						· · · · · · · · · · · · · · · · · · ·				
Rank order (i)	1	2	3	4.	5	6	7	8	9	10
Value	6.8	6.9	7.5	8.1	8.2	8.3	8:4	8.7	8.8	8.9
Sample index	1	1	1.	1	2 .	2	2	2 ·	1	2
$Ex_{(i)}$ (from Tabl	e 9.1 for	n = 10			12	.12	.38	.66		1.54

Hence $C_1 = 2.58$. From Table 10.3 the 5% value of C_1 for a one-sided test (for n = 10 and $n_1 = 5$) is 2.58. The observed C_1 is thus significant at the 5% level.

Wilcoxon (Mann-Whitney) test: Here $R_2 = 36$. Hence $U_{21} = 25 + 15 - 36 = 4$. This is also significant at the 5% level, the critical value of U_{21} for $n_1 = n_2 = 5$ being 4 from Table 10.4.

Since 5D(5,5) is also equal to 4 the hypothesis that the two feeds are equally good cannot be rejected by a two sided Kolmogorov-Smirnov test. It is seen that a two sided Fisher-Yates test or a two sided Wilcoxon (Mann-Whitney) test also fails to reject the hypothesis. When alternatives are two sided one could also use the Wald-Wolfowitz run test.

Wald-Wolfowitz run test: Total number of runs in the serial arrangement given above is 4. This is not significant at the 5% level, the critical value for $n_1 = n_2 = 5$ being 2 from Table 10.5.

c. Matched-pair sample

Consider n pairs of observations (x_i, y_i) i = 1, 2, ..., n and the hypothesis that for each i the distribution of (x_i, y_i) is the same as that of (y_i, x_i)

(i) The sign test

Consider only the $n \leq n$ pairs where $x_i \neq y_i$ and let r' be the number of pairs where $x_i < y_i$. For a given n' the distribution of r', under the given hypothesis, is binomial with $\pi = \frac{1}{2}$ This hypothesis could be tested in the manner discussed in 1.3.

(ii) The Wilcoxon test (Table 10.6)

Compute $d_i = x_i - y_i$. Here again as in the sign test all the n-n' pairs where $d_i = 0$ are dropped out. The remaining d_i are ranked in increasing order of magnitude disregarding sign, the smallest $|d_i|$ receiving rank 1. Then to each rank is affixed the sign of d_i to which it corresponds. Define

T = sum of all ranks with a negative sign,

 $T_{+} = \text{sum of all ranks with a positive sign,}$

 $T = \min \left\{ T_-, T_+ \right\}.$

Table 10.6 gives the 1% and 5% values of T, T_- or T_+ . A computed value of T is significant if it is less than or equal to the value given in Table 10.6.

The choice of the statistic T_- , T_+ or T depends on the type of alternatives one wishes to detect.

Table 10.6 covers values of n' = 6(1)25. For larger values of n' the sampling distribution of T_+ (or equivalently T_-) may be assumed to be normal with

$$mean = \frac{n'(n'+1)}{4},$$

variance =
$$\frac{n'(n'+1)(2n'+1)}{24}$$
.

Note that

$$T_{+}+T_{-}=\frac{n'(n'+1)}{2}$$

Example: The following table gives the yield rate of paddy (in maunds per acre) as observed in ten pairs of concentric circles of radii 2 ft and 4 ft. Examine if the yield rate has been over-estimated by the smaller circle.

sample	e: 1	2	3	4%	5	6 .	. 7	8	.9	10	
2 ft.	6.12	5.39	5.59	6.34	6.29	5.98	5.61	4.43	5.93	5.33	
. 4 ft.	5.50	6.00	4.71	6.12	5.93	5.56	5.41	5.14	5.66	5.67	(x)

Here we have

sample:	1	2	3	. 4	5	6	7	. 8	9 .	10
x-y	-0.62	0.61	-0.88	-0.22	-0.36	-0.42	-0.20	0.71	-0.27	0.34
Rank of x-y	1 8	7(+)	10	2	5	6	1	9(+)	3	4(+)

 $T_{+}=4+9+7=20$. The 5% value of T_{+} (for a one-sided test) for n=10 is 10 from Table 10.6. Hence the observed result is not significant.

d. Spearman's rank correlation coefficient

When n individuals in a sample are ranked according to each of two different characteristics, the association between the characteristics may be measured by Spearman's rank correlation coefficient. This is the ordinary product moment correlation coefficient applied on rank pairs. When there are no tied ranks, the correlation coefficient can be computed by the formula

$$r_{i} = 1 - \frac{6\sum_{i=1}^{n} d_{i}^{2}}{n^{3} - n}$$

where d_i is the difference in the two ranks of the *i*-th individual.

Table 10.7 gives the upper 1% and 5% values of $|r_s|$ for a two-sided test and also the upper 1% and 5% values of r_s for a one-sided upper tail test. The lower 1% and 5% values of r_s for a one-sided lower tail test are obtained by prefixing a negative sign to the corresponding upper tail values.

Table 10.7 covers sample sizes up to n = 10. For n larger than 10, the critical values of r given in Table 7.1 with d.f. v = n-2, may be used as approximate critical values of r_s .

Example: A set of 10 individuals were ranked by two independent examiners with respect to their reasoning abilities. The ranks are given below. Test for association between ranks by the two examiners.

Individual:	1	2	3	4	5	6.	7	8	9	10
Examiner 1:	7	1	3.	5	9	8	4	10	2	, . 6
Examiner 2:		2	4	3	8	10	5	9	. 1	7
d:	. 1	-1	-1	2	1	-2	-1	1	1	-1

$$\Sigma d_i^2 = 16, n^3 - n = 990, r_s = 1 - 96/990 = 0.9030$$

This is significant at the 1% level, the critical value for a two-sided test being 0.794 from Table 10.7.

11.1. MEASUREMENTS DATA

a. Introduction

Control charts are used to detect changes in the mean value (centre of location) and in the variability (dispersion) of a process. The procedure consists in obtaining measurements on a sample of n items, computing chosen measures of location and dispersion, plotting the computed values on appropriate charts and taking decisions (regarding changes in the processes) depending on the positions of the plotted points.

How is a control chart drawn for any particular measure of location or dispersion? Let T represent any such measure based on n observations in a sample. The central line of the control chart for T is drawn at E(T), the expected value of T and the upper and lower control limits at $E(T)+b_1\sigma(T)$ and $E(T)-b_2\sigma(T)$ respectively, where b_1 and b_2 are suitably chosen constants and $\sigma(T)$ is the standard deviation of T. The limits obtained by choosing b_1 , b_2 such that

Probability
$$\{T - E(T) \ge b_1 \sigma(T)\} = \alpha/2$$

Probability $\{T - E(T) \le -b_2 \sigma(T)\} = \alpha/2$

are called α probability limits. Those obtained by choosing $b_1 = b_2 = 3$ are called three sigma limits.

As an example for location, T may be the average x or the median \tilde{x} of the sample. Charts using x and \tilde{x} are called the x chart and \tilde{x} (median) chart respectively. As a measure of dispersion T may be the standard deviation s, or the range R of the sample leading to an s-chart or an R-chart.

Let the true process average and standard deviation be represented by μ and σ . Under the assumption of normality of the observations, the $\sigma(T)$ for each measure T considered in Table 11.1 is found to be a multiple of σ , the process standard deviation. Hence the upper and lower control limits in all these cases can be written as

$$E(T)+z_1\sigma$$
 $E(T)-z_2\sigma$

when μ and σ are specified.

The process mean and standard deviation may not be specified in practice, but may be estimable on the basis of previous data. If the past data are sufficiently numerous, yielding stable estimates of μ and σ , the same formulae $E(T)+z_1\sigma$, $E(T)-z_2\sigma$ for control limits can be used substituting estimates for E(T) and σ .

b. Construction of a control chart

Table 11.1 provides the formulae for E(T), and multipliers of σ or of an estimate of σ for a wide variety of measures, T. The general procedure for constructing a control chart is as follows:

- (i) Decide on the subgroup (or sample) size n.
- (ii) Choose a suitable measure of location and/or a measure of dispersion (see column (1) of Table 11.1 for measures commonly used).

- (iii) (a) If the standards, i.e., the mean and the standard deviation of the process are known, use the formulae in column (3) for E(T), the central line, and the formulae in column (6) for multiplying factors z_1, z_2 . Thus, if we want a control chart for the measure s, the sample standard deviation, the central line is at $c_2\sigma$ and the upper and lower control limits are at $B_2\sigma$ and $B_1\sigma$.
 - (b) If the standards are not known, decide to use one of the alternative estimates of E(T) given in columns (4) and (5) for the central line and one of the alternative estimates \bar{s} , \bar{R} , or \tilde{R} for σ as defined in 11.1c below. The multiplying factors for these estimates are given in columns (7), (8) and (9). Thus, if we want a control chart for the median \tilde{x} choosing \bar{x} as the estimate of μ and choosing \bar{R} as an estimate of σ , the central line is at \bar{x} and the formulae for the upper and lower control limits are, as found from column (8) of Table 11.1,

$$\tilde{\tilde{x}} + F_2 \tilde{R}$$
 and $\tilde{\tilde{x}} - F_2 \tilde{R}$.

(iv) Having chosen the appropriate formula from Table 11.1 we have to find the numerical values of the symbols $A_1, A_2, ..., B_1, B_2, ...$ etc. They depend on the value of n and the nature of control limits required (3 sigma or probability limits). The values of all the symbols of Table 11.1 for 3 sigma limits are given in Table 11.2 for values of n=2 (1) 10 and for some symbols upto n=20. The values of some symbols for probability limits are given in Table 11.3.

c. Estimation of standards

The methods for computing different estimates of μ and σ from past data are as follows. Let $x_1 \ldots x_N$ be the available series of past data. Divide the series into groups of n observations obtaining $k = \lfloor N/n \rfloor$ subgroups omitting if necessary a few observations at the end. It is assumed that N is large compared to n. For each subgroup compute the value of a measure of location and a measure of dispersion as shown in the following table.

In theory we can use any of the 8 estimates of μ in conjunction with any of the four estimates of σ , but in Table 11.1, we have indicated only some of the combinations for which tables exist for computing the control limits. It is also customary to examine the homogeneity of past data before using the estimated values of μ and σ for control limits. This is done by constructing control charts based on the estimates and plotting the subgroup values. Thus if we are computing the subgroup means and standard deviations we may construct an \bar{x} chart using the estimates \bar{x} and \bar{s} . On such a chart we can plot the k consecutive values $\bar{\tau}_1, \ldots, \bar{\tau}_k$ and judge whether they were under control.

median

sub-	original	alten	native measure	es of locati	on	alternative measures of dispersion

	: '		•	•	-	:	:		
龙	$x_{n(k-i)+1}$ \vdots x_{kn}	7 _k ·	\tilde{x}_{k}	$(\Sigma x)_k$	Mk	81.	R_k		
mean		\overline{x}	ž	$\overline{(\Sigma x)}$	\overline{M}		\overline{R}		

ESTIMATION OF STANDARDS FROM PAST DATA

The symbols used are self-explanatory. Thus \tilde{x} is the median of the subgroup medians $\tilde{x}_1, \tilde{x}_2, \ldots \tilde{x}_k$; \tilde{x} is the mean of subgroup means x_1, x_2, \ldots, x_k ; \tilde{s} is the median of subgroup standard deviations s_1, s_2, \ldots, s_k and so on.

providing 8 estimates of u

 (Σx)

providing 4 estimates of σ

11.2. ATTRIBUTES DATA

Instead of providing a measurement such as the length of an item, sometimes it is scored as bad or good, or as within or outside certain gauge limits, or as having a certain number of defects. The relevant formulae for the central line and the 3-sigma limits in such cases are given in Table 11.4.

d and p charts: When an item is scored as good or bad, the quality of a subgroup of n items is judged by the number defective (d) or the proportion defective (p). If the number defective is assumed to have a binomial distribution with the parameter π , then

$$E(p) = \pi, \quad E(d) = n\pi$$

$$\sigma(p) = \sqrt{\pi(1-\pi)/n}, \quad \sigma(d) = \sqrt{n\pi(1-\pi)}$$

which provide the formulae for the central line and the upper and lower control limits for the p and d charts.

If probability limits are required one has to use the cumulative probabilities of the binomial distribution. Let d_{ij} and d_{ij} denote the upper and lower limits for d at a probability $\alpha/2$ on each side. Then they satisfy the equations

$$\sum_{d \, \geqslant \, d_u} \binom{n}{d} \pi^d (1-\pi)^{n-d} \, \leqslant \, \frac{\alpha}{2} \, , \, \sum_{d \, \leqslant \, d_t} \binom{n}{d} \pi^d (1-\pi)^{n-d} \, \leqslant \, \frac{\alpha}{2} \, .$$

The values of d_i and d_u for given n and π can be determined using the entries of Table 1.2. In the case of the p chart the upper and lower propability limits are d_u/n and d_l/n , where d_u and d_l are as determined above.

If the value of π is not specified, an estimate from past data may be substituted in the above formulae. The best estimate of π is p the observed proportion of defective items in the past data. Of course, the control chart for p or d with an estimated π can be used to test the homogeneity of past data by dividing the original series into subgroups of size n and plotting the individual values of p or d for each subgroup.

b-a and b+a or g and h charis. In some cases, an item is scored as above an upper gauge value, as below a lower gauge value or as between the two values. Out of n items let b be the number of items above a given value and a be the number below another given value. The quality of subgroup is judged by g=b-a which is sensitive for a change in the average size of the items and/or h=b+a which is sensitive for a change in the dispersion of the size of the items. The formulae for the central line and upper and lower 3 sigma limits for g and h are given in Table 11.4, where n_1 and n_2 denote the hypothetical proportions of the items below the lower gauge and above the upper gauge value respectively

The determination of probability limits for small values of n is somewhat difficult in the case of b-a. For b+a it is done as in the case of the number defective chart choosing $\pi = \pi_1 + \pi_2$

If the values of π_1 and π_2 are not known they may be estimated by p_1 and p_2 , the observed proportions of items below the lower gauge value and above the upper gauge value respectively. The estimate of $\gamma(=\pi_2-\pi_1)$ is $\bar{g}(=p_2-p_1)$ and the estimate of $\delta(=\pi_1+\pi_2)$ is $\bar{p}(=p_1+p_2)$. The control charts constructed by using the estimated values of γ and δ can be used for testing the homogeneity of past data

11.3. COUNT OF DEFECTS DATA

c, C, \bar{c} charts: The quality of an item such as a glass pane or a piece of cloth of given dimensions is judged by the number of defects (c) on it. On the assumption of a Poisson distribution for c, the mean and variance are each equal to λ , the Poisson parameter. The formulae for the central line and the 3 sigma limits for c the number of defects on a single unit, C the total number of defects on n units and \bar{c} the average number of defects per unit are given in Table 11.5. The probability limits can be obtained by first computing the cumulative probabilities from the individual terms of the Poisson distribution given in Table 2.1.

When the value of λ is not specified it may be estimated from past data by the average number of defects per unit. The homogeneity of past data can be examined by considering subgroups and plotting the successive values of C or \bar{c} on the appropriate chart based on the estimated value of λ .

Note: The constants tabulated in Table 11.2 have been calculated under the assumption that the population distribution is normal. The constants in the general formula of the last column are defined as follows.

$$c_2 = E(s) = \sqrt{2}\Gamma\left(\frac{n}{2}\right) \div \sqrt{n}\Gamma\left(\frac{n-1}{2}\right) \quad c_3 = \sigma_8 = \left[\frac{n-1}{n} - c_2^*\right]^{\frac{1}{2}}, \ d_2 = E(R), \quad d_3 = \sigma_R, \quad d_m = E(\tilde{R}),$$

 $e_2 = d_2/d_m$ where s, R, \tilde{R} , etc are as defined in column (2) of Table 11.1. In the tabulated values of d_m , E(E) is approximated by the median of the distribution of R.

11.4 CUMULATIVE SUM CONTROL CHARTS

a. Introduction

The cumulative sum control chart (cusum chart) is used primarily to maintain current control of a process. Its advantage over the ordinary Shewhart chart is that it may be equally effective at less expense. This stems from the possibility of the cusum control chart picking up a sudden and a persistent change in the process average more rapidly than a comparable Shewhart chart, especially if the change is not large. The concept of Average Run Length (ARL) is used in the design of cusum charts. ARL is defined as the average number of samples plotted at a specified quality level before the chart indicates that the process is off target.

One sided decision interval scheme

Suppose we want to control the process at μ_0 and are interested in detecting changes in the process level in the upward direction. A reference value $k(>\mu_0)$ and a decision interval h are chosen, and the modified cusum is defined as follows. Compute successively

$$s_0 = 0, \quad s_r = \max\{0, s_{r-1} + (x_r - k)\}$$
 ... (1)

where x_r is the r-th observation. The chart indicates corrective action when for the first time $s_r \geqslant h$. If we want to detect shifts in the lower direction, we use

$$s_0 = 0, \ s_r = \min\{0, s_{r-1} + (x_r - k)\}$$
 ... (2)

where $k < \mu_0$. Corrective action is taken when for the first time $s_r \leqslant -h$.

Figure 1 is a nomogram which gives the ARL values for the control scheme (1) for any given value μ of the process level and chosen h, k when the characteristic is distributed normally with unit standard deviation. Suppose the process level is μ , process variability is σ and averages of samples of size n are plotted on the chart. We use L_a curve when $\mu < k$ and the L_r curve when $\mu > k$. We calculate $|k-\mu| \frac{\sqrt{n}}{\sigma}$ and $h \frac{\sqrt{n}}{\sigma}$ and locate these points on the line indicated by $|k-\mu| \frac{\sqrt{n}}{\sigma}$ and the curve indicated by $h \frac{\sqrt{n}}{\sigma}$ respectively and join them by a straight line. The point where this line cuts the L_a or the L_r curve as the case may be gives the ARL value.

Example

Given $\sigma=10$, n=4, k=105 and h=13, find the ARL values for $\mu=100$, .102 and .110.

$$\frac{h\sqrt{n}}{\sigma} = 2.6,$$

|105-100|
$$\frac{\sqrt{n}}{\sigma}$$
 = 1.0 ARL = 830 (from L_a curve), for $\mu = 100$.

$$|105-102| \frac{\sqrt{n}}{\sigma} = 0.6$$
; ARL = 104 (from L_a curve), for $\mu = 102$

| 105-110 |
$$\frac{\sqrt{\tilde{n}}}{\sigma}$$
 = 1.0; ARL = 3.5 (from L_r curve), for μ = 110

Suppose we are given two values of the process level, say μ_0 acceptable level and μ_1 rejectable level, and also the desired ARL values i.e., of L_a and L_r respectively. L_a will be usually large and L_r will be small. There will be a number of combinations of n, k and h to meet these requirements. However, there are a number of advantages to be gained by the use of a central reference value i.e., $k = (\mu_0 + \mu_1)/2$. We shall henceforth choose a reference value which is either central or near central. Table 11.6 which has been extracted from the nomogram gives the values of

$$|k-\mu_1| \frac{\sqrt{\bar{n}}}{\sigma} = |k-\mu_0| \frac{\sqrt{\bar{n}}}{\sigma} = |\mu_1-\mu_0| \frac{\sqrt{\bar{n}}}{2\sigma}$$

and $h\sqrt{n}/\sigma$ for particular values of L_a and L_r when central reference value is used i.e., $k = (\mu_0 + \mu_1)/2$. Then the values of n and h can be computed to design a suitable cusum control scheme.

Example: Design a suitable one sided decision interval scheme such that when $\mu_0 = 4.0$, $\mu_1 = 4.5$ and $\sigma = 1$, the values of L_a and L_r are 500 and 5 respectively

$$k = \frac{4.00 + 4.50}{2} = 4.25, \quad \frac{\mu_1 - \mu_0}{2\sigma} = 0.25$$

From Table 11.6 we find that

$$\frac{(\mu_1 - \mu_0)\sqrt{n}}{2\sigma} = 0.74$$
 and $\frac{h\sqrt{n}}{\sigma} = 3.18$

From the first equation, $0.25\sqrt{n} = 0.74$ or n = 8.76 with the rounded value 9. Then

$$\frac{h\sqrt{n}}{\sigma} = 2.96h = 3.18 \text{ or } h = 1.07$$

V-mask Procedure:

V-mask procedure is used when one is interested in detecting the shifts from the target level μ_0 in either direction. The procedure is as follows. Compute

$$S_0 = 0$$
, $S_r = S_{r-1} + (x_r - \mu_0)$, $r = 1, 2, ...$

and plot S_r against r. A V-mask is super imposed (see figure 2) on the chart with the vertex 0 at a distance d in horizontal plotting intervals ahead of the most recent point P on the chart. If the path of the chart cuts either limb of the V-mask, we conclude that the process is off the target. When the lower limb is cut, an increase in process level is indicated and when the upper limb is cut, a decrease in the process level is indicated. The parameters of the V-mask chart are

 θ the half angle and d the lead distance. The parameters depend very much on the scale of the S_r axis and also on the horizontal distance between two successive plots. As such we define the scale factor w as the horizontal distance between successive points plotted on the chart measured in terms of unit distance on the vertical scale. It has been established that the V-mask procedure is equivalent to simultaneous application of two one-sided decision interval schemes. It is also shown that the ARL of the V-mask (L) is related to L_1 and L_2 , the ARL's of two one sided decision interval schemes, by the formula

$$\frac{1}{L} = \frac{1}{L_1} + \frac{1}{L_2}.$$

The relationship of the parameters of the V-mask and the two one sided decision interval schemes are given by

$$\begin{split} k_1 &= \mu_0 + w \, \tan \, \theta, \quad h_1 = w \, d \, \tan \, \theta; \\ k_2 &= \mu_0 - w \, \tan \, \theta, \quad -h_2 = -w \, d \, \tan \, \theta. \end{split}$$

Hence either the nomogram or Table 11.6 can be used in the design of V-mask control schemes.

The procedure for finding the sample size, half angle θ and lead distance d is as follows:

The acceptable process level is μ_0 and we have two values of μ_1 , the rejectable level: $\mu_1 = \mu_0 \pm \Delta$ where Δ is some positive constant. The values of ARL are specified to be L_a at μ_0 and L_r at $\mu_0 + \Delta$ and $\mu_0 - \Delta$.

- (1) Read from Table 11.6 the values of $\left|\frac{\mu_1-\mu_0}{2}\right|\frac{\sqrt{n}}{\sigma}$ and $\frac{h\sqrt{n}}{\sigma}$ for $2L_a$ and L_r .
- (2) Since $\left|\frac{\mu_1-\mu_0}{2}\right| = \Delta/2$ is known, the value of n is easily computed.

(3)
$$|k-\mu_0| = \left|\frac{\mu_1-\mu_0}{2}\right| = w \tan \theta \text{ or } \theta = \tan^{-1}\left(\frac{|\mu_1-\mu_0|}{2w}\right).$$

(4)
$$h = w d \tan \theta$$
 or $d = \frac{h\sqrt{n}}{\sigma} \div \frac{|\mu_1 - \mu_0|\sqrt{n}}{2\sigma}$.

Example: Devise a suitable V-mask control scheme, given that $\mu_0=4.0$, $\mu_1=4.0\pm0.5$, $\sigma=1$ and $L_a=500$ and $L_r=5$.

Entering the Table 11.6 for $L_{\alpha} = 1000 \, (= 2 \times 500)$ and $L_r = 5$, we get

$$\left| \frac{\mu_1 - \mu_0}{2\sigma} \right| \sqrt{n} = 0.80$$
 and $\frac{h\sqrt{n}}{\sigma} = 3.41$.

Since $|\mu_1 - \mu_2|/2 = 0.25$, $\sigma = 1$, $0.25\sqrt{n} = 0.80$ or n = 10.24 with the rounded off value 11. When the scale factor w = 1, we get from Table 17.7.

$$\theta = \tan^{-1}\left(\frac{|\mu_1 - \mu_0|}{2w}\right) = \tan^{-1}\left(\frac{0.25}{w}\right) = \tan^{-1}\left(0.25\right) = 14^\circ.$$

$$d = \frac{h\sqrt{n}}{\sigma} \div \frac{|\mu_1 - \mu_0|\sqrt{n}}{2\sigma} = \frac{3.41}{0.80} = 4.26$$
 horizontal plotting intervals.

Cusum charts for attributes

When we consider number of defects per sample or proportion defective (when the proportion is sufficiently small), we can use Poisson distribution for the design of cusum control schemes. Table 11.7 (Kemp, Applied Statistics 11, 1962) is useful for this purpose. Let m_a and m_r be the acceptable and rejectable levels of the Poisson parameter. Table 11.7 gives for $R = m_r/m_a = 2.50$, 3.00, 3.50 and 4.00; $L_a = 500$, 250 and 125; $L_r = 5.0$, 7.5 and 10.0, the values of m_a , k and k. In case of proportion defective π we note that $m_a = n\pi_a$ and $m_r = n\pi_r$.

Example:

Given $\pi_a = 0.01$, $\pi_r = 0.04$, $L_a = 500$ and $L_r = 7.50$ design a suitable cusum scheme.

R = 0.04/0.01 = 4. For R = 4, $L_a = 500$, $L_r = 7.50$ we have $m_a = 0.24$, k = 0.6 and h = 2.75.

$$n \times \pi_a = m_a = 0.24 = n \times 0.01$$
 or $n = 24$.

Take samples of size 24 and let x_r be the number of defectives in the r-th sample. Define $s_0 = 0$, $s_r = \max\{0, s_{r-1} + (x_r - 0.6)\}$. Take corrective action when $s_r \ge 2.75$ for the first time.

12.1 CONFIDENCE INTERVALS FOR PARAMETERS.

a. Percentage defective

In sampling with replacement, the number d of defectives in a sample of size n from any lot follows a binomial distribution $b(n, \pi)$ where π is the proportion of defectives in the lot. This distribution also holds good, as an approximation, in sampling without replacement, if the lot size is very large compared to the sample size.

Confidence intervals for π are tabulated in Table 1.3 for $n \leq 30$. Table 12.1 provides 95+% and 99+% confidence intervals for 100π (percentage defective) based on the Clopper-Pearson system, for n = 40, 50, 75, 100(100)500, 1000.

b. Average number of defects

Under fairly general conditions, the number of defects per unit, in units of identical dimension, follows a Poisson distribution.

Two sided 95+% and 99+% confidence intervals for the Poisson mean λ , the average number of defects per unit, are given in Table 2.2.

c. Average measured value of a characteristic

When the measured value of a characteristic is normally distributed as $N(\mu, \sigma^2)$ confidence limits for its average (μ) based on a sample of size n are given by

95% limits: $x \pm 1.96\sigma/\sqrt{n}$ 99% limits: $x \pm 2.58\sigma/\sqrt{n}$

if σ is known.

When σ is not known, the confidence limits for μ will be obtained from the following formula

$$100(1-\alpha)\%$$
 limits: $x \pm t_{\alpha} s / \sqrt{n-1}$

where t_{α} is the two-sided $100\alpha^{\circ}$ point of the *t*-distribution with n-1 d.f. given in Table 4.1 (refer to the bottom row of Table 4.1), and $s = \sqrt{\Sigma(x_i - \bar{x})^2/n}$.

When σ is not known, instead of the sample standard deviation, the sample range R or the mean range \overline{R} from k sub-groups (samples) each of size n may be used along with \overline{x} , to obtain confidence limits for μ . For computing 95% and 99% confidence intervals of the type $\overline{x} \pm h$ \overline{R} , the factor h has been tabulated in Table 12.2 for n=2 (1)15 and k=1 (1)15.

d. Standard deviation of a measured value

Either the sample standard deviation s or the sample range R may be used to obtain the confidence interval for the parameter σ of the normal distribution. Table 12.3 gives factors f_1 and f_2 for computing 95% and 99% confidence intervals for σ , of the type (f_1s, f_2s) . Table 12.4 provides factors g_1 and g_2 for computing 95% and 99% confidence intervals for σ , of the type $(g_1 R, g_2 R)$.

Example. The range of breaking strength as observed in 10 pieces of hard drawn copper wire was 50.2 pounds. To obtain 95% confidence limits for σ .

From Table 12.4, the 95% values of g_1 and g_2 for n=10 are read as 0.209 and 0.597 respectively. Hence 95% confidence limits for σ are $0.209 \times 50.2 = 10.5$ pounds and $0.597 \times 50.2 = 30.0$ pounds.

^{(1), (2), (3):} These values could be in error in the last digit by the maximum amount of ± 1 , ± 3 , ± 1 respectively.

12.2 Tolerance Intervals

a. Introduction

Tolerance interval is constructed from experimental data such that the probability is p that at least a proportion P of the distribution will be enclosed by the interval. For the case of the normal population, Tables 12.5, 12.6, 12.7 and 12.8 give the appropriate factors for constructing tolerance intervals. Table 12.5 is to be used when s is taken as the estimate of σ . The desired limits are then $\bar{x} \pm ks$ where x is the sample mean. Table 12.5 gives the values of the factor k when x and sare computed from a sample of size N for p = 0.75, 0.9, 0.95, 0.99, P = 0.75, 0.90, 0.95, 0.99, 0.999; N = 2(1)27, 30(5)100(10)200(50) 300(100)1000 and $N = \infty$. Table 12.6 is to be used when a single range is used for estimation of σ . Here we use \bar{x} and R where \bar{x} is the mean and R is the range in a sample of size N. The tolerance limits are constructed as $\bar{x} \pm k_1 R$. Table 12.6 gives the factor k_1 for the same values of p and P as in Table 12.5 and for N=2(1)20. Table 12.7 is to be referred when we use the average range of samples of size 4. The tolerance interval is given by $\overline{x} + k_2 \overline{R}$ where \overline{x} is the grand mean and \overline{R} is the mean range in N samples of size 4. Table 12.7 gives the factor k_2 for N=4(1)20(5)30(10)50(25) 125 and $N=\infty$ for the same values of p and P as above. Table 12.8 is to be referred when mean range for samples of size 5 is used. The tolerance interval is given by $x\pm k_3\overline{R}$ where $\overline{\tilde{x}}$ is the grand mean and \overline{R} is mean range in N samples of size 5. Table 12.8 gives the factor k_3 for N = 4(1)20(5)30(10)50(25)100 and $N = \infty$.

Table 12.5 is due to Bowker (Techniques of Statistical Analysis, Statistical Research Group, Columbia University, McGraw-Hill, New York, 1947). Tables 12.6, 12.7 and 12.8 are due to Mitra (Journal of American Statistical Association, 52, 1957).

b. Application

The tolerance intervals are mainly used in quality control work for asserting with a given confidence that a certain minimum proportion of the manufactured products will have the quality characteristic value between these limits.

Example

A sample of 28 tins of hydrogenated oil were taken and net weight was measured (in gms) giving $\bar{x} = 1002$ and s = 12. Find tolerance limits having confidence coefficient 0.95 for 90% of the population.

For n=28, p=0.95, P=0.90, we find from the Table 12.5, k=2.164. Hence the tolerance limits are $1002\pm2.164\times12=976$ to 1028.

13. DISTRIBUTION OF RANGE

13.1 MOMENT CONSTANTS OF THE MEAN DEVIATION AND RANGE

a. Introduction

Let $x_1, x_2, ..., x_n$ denote a random sample of n observations and $\bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$.

Let $x_{(1)}, x_{(2)}, ..., x_{(n)}$ denote the same observations in the ascending order of magnitude. The mean deviation m and the sample range R are defined by

$$m = \frac{1}{n} \sum_{i=1}^{n} |x_i - \bar{x}|$$
 and $R = x_{(n)} - x_{(1)}$.

When the population sampled is normal with standard deviation σ , Table 13.1 gives the expected value, standard deviation and β_1 and β_2 for the distribution of m/σ . This table also gives the expected value (d_2) , standard deviation (d_3) , variance (d_3^2) , β_1 and β_2 , d_2/d_3^2 and d_2^2/d_3^2 for the distribution of the standardised range R/σ .

b. Application

Table 13.1 is useful for estimating σ by mean deviation or range mostly in quality control work. For example since $E(R/\sigma) = d_2$, R/d_2 is an unbiased estimate of σ and the standard error of this estimate is $\sigma d_3/d_2$. Similarly an unbiased estimate of σ can be obtained by dividing the mean deviation by its expected value.

The following table gives the standard errors of different unbiased estimators of σ , based on sample standard deviation, mean deviation and sample range.

STANDARD ERRORS OF DIFFERENT UNBIASED ESTIMATORS OF σ (Expressed in terms of σ as unit)

m. 1 *	a n	M D	Damas	Range estimate
Sample size (n)	S.D. estimate	M.D. estimate	Range estimate	S.D. estimate
2	0.756	0.756	0.756	1.00
3	0.523	0.525	0.525	1.00
4	0.422	0.430	0.427	1.01
5	0.363	0.373	0.372	1.02
6	0.323	0.334	0.335	1.04
7	0.294	0.306	0.308	1.05
8	0.272	0.283	0.288	1.06
9	0.254	0.265	0.272	1.07
10	0.239	0.250	0.259	1.08
12	0,215	0.227	0.239	1.11
15	0.191	0.201	0.218	1.14
20	0.163	0.173	0.195	1.20

It is seen that up to n=10, there is very little to choose between mean deviation and range. Beyond this, relative accuracy of the range estimator falls off progressively. It is customary to estimate σ from the mean range of the observations in a number of small groups. If k samples of r observations each are available and we write the mean value of their ranges as \overline{R} , then \overline{R}/d_2 is an unbiased estimate of σ . The use of factors d_2/d_3^2 and d_2^2/d_3^2 is discussed in section 13.3.

c. Example

Twenty samples of size 5 were taken of a particular component and diameters were measured. The mean range \overline{R} was 0.01435, find an estimate of σ .

From Table 13.1, the value of d_2 for n=5 is 2.326 (correct to 3 decimal places). Hence an estimate of σ is

$$\hat{\sigma} = \frac{\overline{R}}{d_2} = \frac{0.01435}{2.326} = 0.006169.$$

The standard error of the estimate is estimated by

$$\hat{\sigma}d_3/d_2\sqrt{20} = \overline{R}d_3/d_2^2\sqrt{20} = (0.006169)(0.8641)/(4.472136)(2.326)$$

= 0.0005.

The unit is the population standard deviation.

13.2. PERCENTAGE POINTS OF THE DISTRIBUTION OF THE RANGE

a. Introduction

For the case of normal population with standard deviation σ , Table 13. 2 gives for n=2(1)20, the factor $1/d_2$ and some lower and upper percentage points of the distribution of the standardized range R/σ . This table is useful in setting up a control chart for range to check on the variability of a product.

b. Example

The width of slot of terminal blocks is distributed normally with standard deviation 0.001 in. Find 2.5% probability control limit for ranges of sample size 5.

We have for n=5, $d_2=2.326$ and the upper 2.5 percent point is 4.20. Hence the central line for the R chart is $d_2\sigma=0.002326$ and the upper control limit is 0.0042.

TABLE 13.2. PERCENTAGE POINTS OF THE DISTRIBUTION OF THE RANGE

The unit is the population standard deviation.

Estimate of $\sigma = \text{range}$ (or mean range) in a sample of n observations $\times 1/d_2$.

13.3 Values Associated with the Distribution of the Average Range

a. Introduction

Suppose we have k samples each of size n from a normal population with standard deviation σ . Let $R_1, R_2, ..., R_k$ be the sample ranges and \overline{R} their average. Patnaik (Biometrika, 1950, 37) showed that $\nu(\overline{R}/d_2^*)^2/\sigma^2$ is approximately distributed as χ^2 with ν degrees of freedom where the scale factor d_2^* and the equivalent degrees of freedom ν are functions of n and k. These functions are given in Table 13.3 for n = 1(1)15.

b Application

The significance of Patnaik's work is then that in any analysis using s, we can replace s by the more readily computed \overline{R}/d_2^* . This provides shortcut tests involving the use of range or mean ranges instead of mean squares. Some of these are : analysis of variance, substitute F tests, substitute t tests etc.

c. Example

The following are data on weight of antibiotic filled in vials (in some coded units). Between the morning and the afternoon production runs, the filling machine was reset and there was some question as to whether the average level was same for both the periods. There is no reason, however, to believe that variation in weight was different for the morning and afternoon runs.

Morning run sample	Afternoon run sample
22.0	22.5
22.5	19.5
22.5	22.5
24.0	22,0
23.5	21.0
$x_1 = 22.9$	$x_2 = 21.5$
$R_1 = 2.0$	$R_2 = 3.0, \bar{R} = 2.5$

From Table 13.3, for k = 2, n = 5, we have $d_2^* = 2.4$ and $\nu = 7.5$.

$$t = \frac{\sqrt{n}|\bar{x}_1 - \bar{x}_2|}{\sqrt{2}(\bar{R}/d_2^*)} = \frac{\sqrt{5}|22.9 - 21.5|}{\sqrt{2}(2.5/2.4)} = 2.12$$

The critical value of t at 5% level of significance for 7.5 degrees of freedom (from Table 4.1) is about 2.33, indicating that the process level was same for both the runs.

d. Unequal sample sizes

In case of k samples based on unequal sample sizes n_i (i = 1, 2, ..., k), an estimate of σ may be obtained from the mean weighted range

$$\begin{array}{c} \sum\limits_{i=1}^k R_i(d_2/d_3^2) \\ \sum\limits_{i=1}^k (d_2^2/d_3^2) + \frac{1}{2} \end{array}$$

where the factors d_2/d_3^2 and d_2^2/d_3^2 are given in Table 13.1. This quantity is approximately distributed as the root mean source estimator s for $v = \frac{1}{2} \sum_{i=1}^{2} d_2^2/d_3^2$ degrees of freedom.

TABLE 13.3. VALUES ASSOCIATED WITH THE DISTRIBUTION OF THE AVERAGE RANGE*

 $[\nu(\vec{R}/d_2^*)^2/\sigma^2]$ is distributed approximately as χ^2 with ν degrees of freedom; \vec{B} is the average range of k subgroups, each of size (n)Size of sample (n

* In general the degrees of freedom will be given approximately by the reciprocal of $(-2+2\sqrt{1+2(c.v.)^2}/k)$ where c.v. is the coefficient of variation $(d_j d_2)$ of the range and k is the number of subgroups. Also d_2^* is given approximately by d_2 (i.e., the infinity value of d_2^*) times $(1+1/4\nu)$. Values of ν are also very readily built up from the constant differences.

Note: c.d = constant difference.

13.4. PERCENTAGE POINTS OF THE STUDENTIZED RANGE

a. Introduction

The studentized range used in tests of means is defined as $q = R/s_{\nu}$, where s_{ν}^2 is an independent mean-square estimate of σ^2 based on ν degrees of freedom. Table 13.4 gives lower and upper 1% and 5% points when the population sampled is normal. The entries in the table correspond to a given number of degrees of freedom for s and the sample size for R.

b. Application

The main use of this statistic is in analysis of variance where it serves as an alternative to the F test. In the simplest case when there are k groups each of r observations, we compute the value of the statistic $q = \sqrt{r(x_{(k)} - x_{(1)})}/s$. Where $x_{(k)}$ and $x_{(1)}$ are the largest and smallest group means respectively and s^2 is the error mean square in an analysis of variance table. We get the critical value of q by reading the upper percentage point for k(r-1) degrees of freedom and sample size k. However this table in conjunction with Table 13.3 provide short cut tests in analysis of variance through use of range. For this purpose, we substitute R/d_2^* for s where R is the mean of the ranges of k groups and d_2^* is an appropriate factor obtained from Table 13.3 for k samples each of size r. The equivalent degrees of freedom r is also read from this table. The critical value of the statistic $q = \sqrt{r(x_{(k)} - x_{(1)})/(R/d_2^*)}$ is obtained by reading the upper percentage point of the studentized range for r degrees of freedom and sample size r.

c. Example

The melting point of a chemical was determined thrice on each of four thermometers:

		Thermo	meters		
. 7	1	2	3	4	•
-	174.0	173.0	171.5	173.5	
	173.0	172.0.	171.0	171.0	
	173.5	173.0	173.0	172.5	
æ	173 5	172:67	171.83	172.33	$\max \bar{x} = 173.5$, $\min \bar{x} = 171.83$
R	1-0	1.0	2.0	2.5	$\overline{R} = 1.625$

MELTING POINT IN DEGREES CENTIGRADE

Do the thermometers read differently ?

We have from Table 13.3 for 4 samples and each of size 3, $d_2^* = 1.75$ and v = 7.5

$$q = \frac{\sqrt{3}(173.5 - 171.83)}{(1.625/1.75)} = 3.12$$

From Table 13.4, the upper 5% point for studentized range for sample size 4 and for 7.5 degrees of freedom (by linear interpolation) is 4.61. Hence this test does not lead to a rejection of the null hypotheses.

n is the size of the sample from which the range is obtained and v is the number of degrees of freedom of sp.

à. Lagrange's formula

Given the values of a function f(x) at $x = x_i$ (i = 1, 2, ..., m), the interpolated value at any value of x is given by formula

$$f(x) = \sum_{i=1}^{m} A_i(x) f(x_i)$$

$$A_i(x) = \frac{(x-x_1)(x-x_2) \dots (x-x_{i-1})(x-x_{i+1}) \dots (x-x_m)}{(x_i-x_1)(x_i-x_2) \dots (x_i-x_{i-1})(x_i-x_{i+1}) \dots (x_i-x_m)}$$

This formula due to Lagrange gives directly the equation to the (m-1)-th degree polynomial which coincides with f(x) at the chosen points.

The coefficients $A_i(x)$ are tabulated in Tables 14.1 to 14.4 for the special case where the chosen arguments x_i are at equal intervals and for m=3, 4, 5 and 6. These tables will be found very useful for polynomial interpolation since they avoid the computation of a table of differences (see chapter VI of Part I).

b. Application

Suppose a function f(x) is tabulated at intervals of 10, say at x = 30, 40, 50, 60, 70, 80, ..., and the value of the function is required at 52. Let us decide on a four point interpolation formula (m = 4) and choose the arguments 40, 50, 60, 70. In Table 14.2 the four arguments are always written as -1, 0, 1, 2, so that a suitable translation and scale transformation is required to apply the formula. In the present case the origin is 50 and the scale is 10, the width of the interval of tabulation. Now we compute u = (52-50)/10=0.20, subtracting the value of the origin and dividing by the width of interval. Reading from Table 14.2 we find the values of A_{-1} , A_0 , A_1 , A_2 corresponding to u = 0.20. Then the interpolated value for f(52) is $A_{-1} f(40) + A_0 f(50) + A_1 f(60) + A_2 f(70)$. We could have chosen any set of four consecutive arguments. But it is better, if possible, to choose the arguments symmetrically about the interval containing 52.

Example. The following are the 1% values of chi-square for different degrees of freedom.

d.f.	χ^2
30	14.95
40	22,16
50	29.71
60	37.49
70	45.44
80	53.54
90	61.76
100	70.07

Find by interpolation the values of χ^2 for (i) 52 d.f. and (ii) 33 d.f.

(I) EVALUATION OF THE 1% VALUE OF χ² FOR 52 D.F. USING 4-POINT INTERPOLATION (TABLE 14.2)

$$u = \frac{52 - 50}{10} = 0.20$$

argument x	f(x)	coefficients for $u = 0.20$	col. (2)×col. (3)
(1).	(2)	(3),	(4)
40	22.16	A_10.048	-1.0637
50	29.71	$A_0 = 0.864$	25.6694
60	37.49	$A_1 = 0.216$	8.0978
70	45.44	$A_1 = -0.032$	-1.4541
total .	•	1.000	31.2494 (Required val

(II) EVALUATION OF THE 1% VALUE OF χ^2 FOR 33 D.F. USING 4-POINT INTERPOLATION (TABLE 14.2)

$$u = \frac{33 - 40}{10} = -0.70$$

argument x	f(x)	$\begin{array}{c} \text{coefficient} \\ \text{for } u = -0.70 \end{array}$	col. (2) ×col. (3)
(1)	(2)	(3)	(4)
30	14.95	$A_{-1} = 0.5355$	8.0057
40	22.16	$A_0 = 0.6885$	15.2572
50 ·	29.71	$A_1 = -0.2835$	-8.4228
- 60 ,	37.49	$A_2 = 0.0595$	2.2307
total		1.0000	17.0708 (Required value)

In this case it is not possible to choose tabular values symmetrically on either side of x. The four tabular arguments closest to x are 30, 40, 50 and 60.

Note: If the arguments chosen are $x_1 < x_2 < x_3$ and interpolation is required at $x(x_2 < x < x_3)$, compute $u = (x-x_2)/h$, where $h = x_2 - x_1 = x_3 - x_2$. Read the three entries A_{-1} , A_0 , A_1 corresponding to u. Then the interpolated value is $A_{-1}f(x_1) + A_0 f(x_2) + A_1 f(x_3$. It x is such that $x_1 < x < x_2$, then compute $v = (x_2 - x)/h$ and use the formula $A_{-1}f(x_3) + A_0 f(x_2) + A_1 f(x_3)$.

Note For values of u in the right hand side column of the tables the coefficients are to be read as indicated in the bottom row of the tables. Thus for u = .74, $A_{-1} = -.0404040$, $A_0 = .2850120 A_1 = .8111889$, $A_2 = -.0557960$.

Note: If the arguments chosen are $x_1 < x_2 < x_3 < x_4 < x_5$ and interpolation is required at $x(x_3 < x < x_4)$, compute $u = (x - x_3)/h$, where h is the interval of the argument. Read the entries A_{-2} , A_{-1} , A_0 , A_1 , A_2 , corresponding to u. Then the interpolated value is $A_{-2}f(x_1) + A_{-1}f(x_2) + A_0f(x_3) + A_1f(x_4) + A_2f(x_5)$. If x is such that $x_2 < x < x_3$, then compute $u = (x_3 - x)/h$ and use the formula $A_{-2}f(x_5) + A_{-1}f(x_4) + A_0f(x_5) + A_1f(x_5) + A_2f(x_5)$.

	A_3	A_2	A_1	A L	. A_1	AL9	1

Note. If the arguments chosen are $x_1 < x_2 < x_3 < x_4 < x_5 < x_6$ and interpolation is required at x such that $x_3 < x < x_4$, compute $u = (x - x_3)/\hbar$ where h is the interval of the argument. Then read the entries A_{-2} , A_{-1} , A_0 , A_1 , A_2 and A_3 corresponding to u and use the formula

 $A_{-2} f(x_1) + A_{-1} f(x_2) + A_0 f(x_3) + A_1 f(x_4) + A_2 f(x_5) + A_3 f(x_6).$

For values of u in the right hand side column of the table, the coefficients are to be read as indicated in the bottom row of the table. Thus for u = .59, $A_{-2} = .0108915052$, $A_{-1} = -.0887075421$, $A_0 = .4781186167$, $A_1 = .6880243508$, $A_2 = -.1000319092$, $A_3 = .0117049786$,

15.1. COEFFICIENTS FOR EQUISPACED ORDINATES

a. Introduction

For evaluating an integral $\int_{c}^{d} f(x)dx$ knowing only the values (ordinates) of f(x) at equidistant values of x tabulated at intervals of h, the formula used is a weighted linear combination of the ordinates. Some well known and simple formulae are already given in Chapter VI of Part I. For a general formula using a polynomial approximation of the maximum degree for f(x), the compounding coefficients, which (apart from the multiplier h) depend upon the number and the position of the ordinates, are given in Table 15.1. As regards the position of ordinates, relative to interval (c, d), three types of situations are considered.

- A. (2m-1) internal and the two terminal ordinates at c and d.
- B. (2m-1) internal, two terminal and two external ordinates at c-h and d+h.
- C. (2m-1) internal, two terminal and four external ordinates at c-2h, c-h, d+h and d+2h.

Coefficients are given for m = 1, 2, 3, 4 and 5 in the case of A and B type of formulae and for m = 1, 2, 3, and 4 in the case of C type.

In Table 15.1, f(a) is the ordinate at the midpoint a of the interval (c, d), f(a+h) are the ordinates at the points a+h and a-h etc.

b. Application

To evaluate $\int_{2.5}^{4.5} \frac{1}{\sqrt{(1.5)}} e^{-x} \sqrt{x} dx$ using ordinates tabulated at an interval of 0.5.

Here h = 0.5 and and the number of internal and terminal ordinates available is 5 so that 2m+1=5 or m=2. The computations are as follows:

ar	f(x)	coefficients from Table 15.1 for $m=2$ for type of formula				
140 ·	<i>f</i> (<i>w</i>)	A no external ordinate	B two external ordinates	C four external ordinates		
1,5	0.308360			13		
2.0	0.215963	. —	-8	-224		
c = 2.5	0.146450	· · . 14	342	5494		
3.0	0.097304	64	1224	17632		
a = 3.5	0.063746	24	.664	10870		
4.0	0.041335	64	1224	17632		
d = 4.5	0.026591	14	342	5494		
5.0	0.017001	· —	-8	-224		
5.5	0.010815			13		
,	divisor :	45	945	14175		

Using A type formula the required integral is given by

 $h[14 \times 0.146450 + 64 \times 0.097304 + ...] \div 45$ = $0.5 \times 12.825374 \div 45 = 0.142504$.

€ .	$\int_{-\infty}^{a+4h} f(x) dx$	B. 2 external	2544	888192	161664	670656	154228	-2368		467775
	4-4/	C. 4 external	. 250827024	994411008	356903280	854897920	228685476	-6534912	275216	638512875
10	ALKB	A. no external	2136840	-1302750	1362000	-242625	531500	80335		299376
(11)	$\left \int\limits_{a-sh}^{a-sh}f(x)dx\right _{1}$	B. 2 external	3577456680	-2488912200	2153747250	-561143500	669257100	71569620	1346350	326918592

Note: To evaluate $\int_{\mathbb{R}}^{a+mh} f(x)dx$ by numerical integration choose the type of formula (A, B, C), compute the weighted sum of ordinates (values

of f(x)) using the coefficients (weights) given in Table 15.1, multiply by h, the length of the interval of tabulation, and divide by the divisor in the last column. Note that f(a) is the middle ordinate and that f(a+ih) and f(a-ih) have the same weight coefficients.

*The figure within brackets indicates the number of internal and terminal ordinates.

If ordinates at 2.0 and 5.0 are used in addition to internal and terminal ordinates (B type formula) the integral is

$$h[(-8) \times 0.215963 + 342 \times 0.146450 + ...] \div 945$$

= $0.5 \times 269.339118 \div 945 = 0.142507$.

If ordinates at 1.5, 2.0, 5.0 and 5.5 are used in addition to internal and terminal ordinates, (C type formula) the integral is

$$h[13 \times 0.308360 + (-224) \times 0.215963 + ...] \div 14175$$

= $0.5 \times 4040.054461 \div 14175 \stackrel{*}{=} 0.142506$.

15.2. Abscissae and Weight Coefficients in Gaussian Quadratube Formulae

a. Introduction

The quadrature formulae given in Table 15.1 are useful when the values of the function to be integrated are known (tabulated) at equispaced values of the abscissa. But if such a table is not available and the function itself has to be evaluated at selected values of the abscissa, one can use more precise quadrature formulae due to Gauss, which specify an optimum choice of the abscissa for this purpose. To apply the formulae given in Tables 15.2.—15.4, the values of the function are computed at the specified values of the abscissa and then a linear combination of these values is taken using the weight coefficients.

b. n-point Gauss-Legendre formula

$$\int_{-1}^{1} f(x)dx = g_1 f(x_1) + g_2 f(x_2) + \ldots + g_n f(x_n).$$

This formula is useful for evaluating definite integrals of the type $\int_{-1}^{1} f(x)dx$. The values of x where the function f(x) has to be evaluated and the corresponding coefficients g are given in Table 15.2, for any chosen value of n=2(1)16. Note that integration in any finite range can be reduced to integration over the range (-1, 1) by suitable transformation of the variable, so that Table 15.2 is useful in evaluating integrals of the form $\int_{-1}^{b} f(x)dx$.

c. n-point Gauss-Laguerre formula

$$\int_{0}^{\infty} e^{-x} f(x) dx = l_{1} f(x_{1}) + l_{2} f(x_{2}) + \ldots + l_{n} f(x_{n}).$$

This formula is useful for evaluating definite integrals of the type $\int_0^\infty e^{-x} f(x) dx$. The values of x where the function f(x) has to be evaluated together with the corresponding coefficients l are given in Table 15.3, for any chosen value of n = 2(1)10.

d. n-point Gauss-Hermite formula

$$\int_{-\infty}^{\infty} e^{-x^2} f(x) dx = h_1 f(x_1) + h_2 f(x) + \dots + h_n f(x_n).$$

This formula is useful for evaluating definite integrals of the type $\int_{-\infty}^{\infty} e^{-x^2} f(x) dx$. The values of x where the function f(x) has to be evaluated together with the corresponding coefficients h are given in Table 15.4, for any chosen value of n = 2(1)10.

a. Introduction

Consider the following polynomials due to Tchebycheff

$$\phi_0(x) = 1$$

$$\phi_1(x) = x$$

$$\phi_2(x) = x^2 - \frac{(n^2 - 1)}{12}$$

$$\phi_3(x) = x^3 - \frac{(3n^2 - 7)x}{20}$$

$$\phi_4(x) = x^4 - \frac{(3n^2 - 13)x^2}{14} + \frac{3(n^2 - 1)(n^2 - 9)}{560}$$

$$\phi_5(x) = x^5 - \frac{5(n^2 - 7)x^3}{18} + \frac{(15n^4 - 230n^2 + 407)x}{1008}$$

$$\phi_6(x) = x^6 - \frac{5(3n^3 - 31)x^4}{44} + \frac{(5n^4 - 110n^2 + 329)x^2}{176}$$

$$- \frac{5(n^2 - 1)(n^2 - 9)(n^2 - 25)}{14784}$$

Observe that

$$\phi_j(x)=(-1)^j\,\phi_j(-x).$$

These polynomials have the following orthogonality property

If x ranges over the n values $t-\frac{n+1}{2}$ (t=1, 2, ..., n), n being an integer $\sum_{x} \phi_{i}(x) \phi_{j}(x) = 0 \text{ whenever } i \neq j.$

Let
$$\sum_{x} [\phi_i(x)]^2 = A_i$$
. Then the first six values of A_i are

$$A_{0} = n$$

$$A_{1} = n(n^{2}-1)/12$$

$$A_{2} = n(n^{2}-1)(n^{2}-4)/180$$

$$A_{3} = n(n^{2}-1)(n^{2}-4)(n^{2}-9)/2800$$

$$A_{4} = n(n^{2}-1)(n^{2}-4)(n^{2}-9)(n^{2}-16)/44100$$

$$A_{5} = n(n^{2}-1)(n^{2}-4)(n^{2}-9)(n^{2}-16)(n^{2}-25)/698544$$

$$A_{6} = n(n^{2}-1)(n^{2}-4)(n^{2}-9)(n^{2}-16)(n^{2}-25)(n^{2}-36)/11099088.$$

Values of $\phi_i(x)$ with some modification (see iii below) are given in Table 16.1 for i = 1(1)5 and n = 3(1)30. The following points should be noted.

- (i) The table provides polynomial values only for those n values of x given by $x = t \frac{n+1}{2}$, (t = 1, 2, ..., n).
- (ii) To save space, however, for values of $n \ge 13$, arguments covering the half range corresponding to $t = 1, 2, ..., \left[\frac{n+1}{2}\right]$ only are given; values for the other half are to be obtained from the symmetry (antisymmetry) relation, $\phi_i(x) = (-1)^i \phi_i(-x)$.
- (iii) To avoid fractional values, the polynomials $\xi_i(x) = \lambda_i \phi_i(x)$ instead of $\phi_i(x)$ have been tabulated and the constants λ_i are shown in the bottom line of each section of Table 16.1. The line just above the bottom line shows values of $\lambda_i^2 A_i = B_i$. Thus to obtain the value of $\phi_i(x)$, if necessary, the tabulated value $\xi_i(x)$ has to be divided by λ_i . Such a computation is unnecessary in practice, and one can use the values of $\xi_i(x)$ directly as shown in the illustrative example.
- (iv) The argument x is not explicitly shown in the table but the ξ_1 column, in fact, gives x for odd values of n and 2x for even values of n.

The tabulated values are useful in fitting polynomials of successive degrees, in stages, if necessary, to observed data. The values of x, the abscissa at which the argument y is observed, should, however, be at equal intervals.

b. Application

An experiment was conducted in a randomised block layout to test whether subjecting seeds to a temperature treatment before planting has any effect on yield. Data on yield per plot at various levels of temperature for seed treatment are summarised as follows:

temperature (°F)	60	75	80 .	105	120
mean yield	60.74	80.00	87.90	89.48	80.60

ANALYSIS OF VARIANCE (for randomised block design)

source	đ.f.	. 8.8.	m.s.	1 F
blocks	4	877.56	219.39	86.37
treatments	4	2616.30	654.07	257.51
error	16	40.60	2.54	

Analyse the results to find the optimum temperature for treatment of seeds.

(i) Fitting a polynomial regression (upto fourth degree) of mean yield per plot on temperature

All the successive four stages of fitting the polynomial giving the regression coefficients on the linear, quadratic, cubic and quartic terms are shown below:

temperature	e mean yield	from Table 16.1 for $n=5$				
	<i>y</i> —	ξı	ξ2	ξ 3	ξ,	
60	60.74	-2	2	-1	1	
75	80.00	-1	± 1	2	-4	
90	87.90	0	-2	0	6	
105	89.48	1	-1	-2	-4	
120	80.60	. 2	2	1	1	
	$\Sigma y \xi$	49.20	-62.60	0.90	-9.18	
\boldsymbol{B}		10	14	10	70	
regression c	oefficient $\Sigma y \xi/B$	4.92	-4.4714	0.09	-0.131	
sum of squa		242.064	279.912	0.081	1.204	

Thus we have the ANOVA table for testing the significance of the regression coefficients.

Since y is the mean of 5 observations each sum of squares given in the last row of the above table is multiplied by 5 for purpose of analysis of variance test.

source	d.f.	8.8.	m.s.	m.s.	8.8.	d.f.	source
linear	1	1210.32	1210.32	468.66	1405.98	3	residual 1
quadratic	[1	1399.56	1399.56	3.21	6.42	2	residual 2
cubic	1	0.40	0.40	6.02	6.02	.1	residual 3
quartic	. 1.	6.02	6.02		*		
total (treatments)	• 4	2616.30					
error .	16	40.60	2.54	2.54	40.60	16	error

The residual after fitting the linear terms is 2616.30-1210.32=1405.98 on 3 d.f. Similarly the residual after fitting the linear and quadratic terms is 1405.98-1399.56=6.42 and so on. Each residual is tested against error, successively starting from residual 1. Residual 2 is unimportant since the variance ratio 3.21/2.54 is not large enough on 2 and 16 d.f. We may normally stop at this stage and infer that a quadratic fit is sufficient.

The equation to the parabola is (using the regression coefficients computed earlier),

$$Y=79.744+4.92\xi_1-4.4714\xi_2.$$
 Since
$$\xi_1=x=(t-90)/15,$$

$$\xi_2=x^2-2=[(t-90)^2/225]-2,$$
 we have
$$Y=88.6868+0.3280(t-90)-0.0199\ (t-90)^2.$$

By equating the derivative with respect to t to zero

$$0.0398(t-90) = 0.3280$$

or, the maximum of Y is attained at t = 90 + 8.24 = 98.24° F.

(ii) Standard error of an estimated yield

The estimated mean yield at temperature $t = 80^{\circ}F$ (say) is given by

$$79.744 + 4.92\xi_1 - 4.4714\xi_2 = 83.42$$

where

$$\xi_1 = \frac{80 - 90}{15} = -0.6667$$

and

$$\xi_2 = \xi_1^2 - 2 = -1.5556.$$

The sampling variance of the estimate is

$$\sigma^{2} \left[\frac{1}{n} + \frac{\xi_{1}^{2}}{B_{1}} + \frac{\xi_{2}^{2}}{B_{2}} \right] = \sigma^{2}(0.0400 + 0.0444 + 0.1728)$$
$$= 0.2572\sigma^{2}.$$

(It may be noted that the variance of an individual regression coefficient b_i is σ^2/B_i and that the b's are mutually uncorrelated).

(iii) Confidence interval for temperature τ at which yield is a maximum

The value of τ is given by the equation

$$\frac{b_1}{15} + \frac{2b_2}{225}(\tau - 90) = 0.$$

The sampling variance of the expression on the left hand side is

$$\sigma^2 \left[\begin{array}{c} \frac{1}{(15)^2 B_1} + \frac{4(\tau - 90)^2}{(225)^2 B_2} \end{array} \right]$$

Consider the inequality

$$\frac{\left|\frac{b_1}{15} + \frac{2b_2}{225}(\tau - 90)\right|}{\sqrt{\frac{1}{B_1(15)^2} + \frac{4(\tau - 90)^2}{B_2(225)^2}}} \leqslant 2.120s$$

where s^2 is the estimate of σ^2 (the error m.s. in the ANOVA table, with 16 d.f.) and 2.120 is the 5% point of Student's t with 16 d.f. This leads to a quadratic in $(\tau-90)$, whose roots provide 95% confidence limits for τ . In this particular example the limits are 96.08 and 101.13.

c. Some other tables

 $r = 1(1) 25].$

FORMULAE AND TABLES FOR STATISTICAL WORK TABLE 16.1. ORTHOGONAL POLYNOMIALS

From n=13, the polynomial values are tabulated for the first $\left[\frac{n+1}{2}\right]$ values of the argument. The other values are obtained by symmetry for the even order polynomials and antisymmetry for the odd order polynomials. Note that $\xi_i(x) = (-1)^i \, \xi_i(-x)$.

Table 17.1 gives the squares of natural numbers upto 999. The same table can be used to find approximate square roots of numbers, correct upto 3 significant digits, by reading in the reverse way. If x is the given number and x_0 is the approximate square root read from Table 171, then a second approximation correct upto 6 significant digits is

$$x_1 = \frac{1}{2} \left(x_0 + \frac{x}{x_0} \right)$$

and a third approximation correct to 12 significant digits is

$$x_2 = \frac{1}{2} \left(x_1 + \frac{x}{x_1} \right)$$

Example 1. To compute $\sqrt{83}$.

To make an effective use of the Table we find $\sqrt{830000}$, making a 6 digited number, and divide the result by 100. From Table 17.1 we find that $911^2 = 829921$ closest to 830000, so that 911 is a first approximation. The second approximation is

$$\frac{1}{2} \left(911 + \frac{830000}{911} \right) = 911.043$$

Dividing by 100, $\sqrt{83} = 9.11043$ correct to six significant digits.

Example 2. To compute $\sqrt{831}$.

Since the number of digits is odd, we consider the five digited number 83100 multiplying the original number by hundred. Now $288^2 = 82944$, so that $x_0 = 288$ and

$$x_1 = \frac{1}{2} \left(288 + \frac{83100}{288} \right) = 288.144$$

Dividing by 10, $\sqrt{831} = 28.8144$ correct to six significant figures.

Example 3. To compute $\sqrt{7134268.17}$.

Since $267^2 = 71289$, we take $x_0 = 2670$. The second approximation is

$$\frac{1}{2}$$
 $\left(2670 + \frac{7134268.17}{2670}\right) = 2671.01$ (correct to six digits).

Example 4. To compute $\sqrt{71342681.7}$.

Since $845^2 = 714025$, we take $x_0 = 8450$. The second approximation is

$$\frac{1}{2} \left(8450 + \frac{71342681.7}{8450} \right) = 8446.46$$
 (correct to six digits).

Table 17.3 is similarly useful in finding cube roots. Thus if it be required to find the cube root of a number x, we find from Table 17.3 the two digited number x_0 whose cube is closest to x. The second approximation is $x_1 = \frac{1}{3} \left(2x_0 + \frac{n}{x_0^2} \right)$ correct to four significant digits.

Some tables in this Chapter are not preceded by notes. Such tables are self-explanatory.

17.5. Conversion of Number Systems

a. Introduction

Most of the digital computers carry out the arithmetical operations in number systems such as the binary (radix 2), ternary (radix 3), octal (radix 8) and hexadecimal (radix 16). Decimal numbers (radix 10) have, therefore, to be converted to other systems at the stage of input into the machine and the results at the stage of output have to be converted back into the decimal system. Table 17.5 which furnishes positive and negative powers of 2, 3, 8 and 16, is useful for this purpose. The table also gives three digited binary equivalents for numbers 0 to 7 and four digited binary equivalents for numbers 0 to 15.

b. Conversion between the decimal and other systems

Example 1. The number

 $(367.6102)_8$

in the octal system is equivalent to

$$3 \times 8^{2} + 6 \times 8 + 7 \times 8^{0} + 6 \times 8^{-1} + 1 \times 8^{-2} + 0 \times 8^{-3} + 2 \times 8^{-4}$$

$$= (247.76113281 \dots)_{10}$$

in the decimal system. To arrive at this value, the positive and negative powers of 8 have been used from Table 17.5 (powers of eight).

Example 2. To convert (247.76113)₁₀ into octal and hexadecimal systems. The integral part 247 and the decimal part .76113 have to be considered separately. To convert the former into the octal system, it is first divided by 8 and the remainder noted, the quotient is then divided by 8 and the remainder again noted; this is continued until the quotient obtained is zero. Thus,

·	quotient	remainder
$247 \div 8$	30	7
30 ÷ 8	3 ··	. 6
$3 \div 8$	0	3

Collecting the remainders,

$$(247)_{10} = (367)_8.$$

As regards the decimal part .76113, repeated multiplication by 8, each time omitting the integer in the unit's place, is carried out as follows:

$$.76113 \times 8 = 6.08904$$

 $.08904 \times 8 = 0.71232$
 $.08904 \times 8 = 5.69856$

yielding $(.76113)_{10} = (.605...)_8$. The final answer is obtained by putting the two conversions together. Thus, $(247.76113)_{10} = (367.605,...)_8$.

In the hexadecimal system there are 16 symbols. The symbols 0, 1, ..., 9 may be used for the digits 0, ..., 9 and t, u, v, w, x, y for 10, 11, 12, 13, 14, 15. The conversion of

(247:76113)10 is done as follows:

quotient remainder 247
$$\div$$
 16 15 7
15 \div 16 0 15 = y
(247)₁₀ = $(y7)_{16}$
.76113×16 = 12.17808
.17808×16 = 2.84928
.84928×16 = 13.58848
...
(.76113)₁₀ = $(v2w...)_{16}$
(247.76113)₁₀ = $(y7.v2w...)_{16}$

Example 3. To convert $(1000111000)_2$ in the binary system to decimal system. $1 \times 2^9 + 1 \times 2^5 + 1 \times 2^4 + 1 \times 2^3 = (568)_{10}$ in the decimal system as obtained by using the powers of 2 given in Table 17.5 (powers of 2). Similarly,

$$(1100.1101)$$

$$=2^{3}+2^{2}+2^{-1}+2^{-2}+2^{-4}=(12.8125)_{10}$$

The conversion from decimal to binary system is done by successive divisions and multiplications by 2 of the integral and decimal parts respectively as in example 2.

b. Conversion between the binary and octal or hexadecimal systems

Example 4. Convert (1000111000)₂ into octal system. This is done very easily by breaking the given number into sets of 3 digits and writing down the octal equivalent of each set using Table 17.5 (binary equivalents). When an incomplete set is found at the beginning, zeros are placed to complete it. Thus,

is written 001,000,111,000with octal equivalents 1 0 7 0giving $(1,000,111,000)_2 = (1070)_8$

The conversion from octal to binary system consists in simply replacing each octal digit by the corresponding triplet of the binary system using Table 17.5. Thus,

$$(1 \ 4 \ 6)_8 = (001, \ 100, \ 110)_2 = (1100110)_2$$

Example 5. Convert (1100011.1011)₂ into octal system. The division into sets is done as follows:

starting from the left for digits preceding the binary point and from the right for digits following the binary point. The incomplete sets are completed and the octal equivalents of the sets are written

001, 100, 011. 101, 100
1 4 3. 5 4
(1100011.1011)₂ =
$$(143.54)_8$$

Thus,

Example 6. Convert (1100011.1011)₂ into hexadecimal system. The procedure using the equivalents given in Table 17.5 (binary equivalents) is the same as inexample 5.

Such simple methods are not generally available for conversion from one system to another. To convert a number with radix b to one with radix c, a general procedure is to convert the number with radix b to decimal system and then convert it to radix c.

Tangents are recorded at intervals of one degree while sines at intervals of six minutes. The values of sines for other values of the argument can be obtained by interpolation using the columns for proportional parts. Thus sin 14°0′+proportional parts for 1′=.24362+.00028=.24475. sin 14°10′=sin 14°12′-proportional part for 2′=.24531—.00056=.24475.

TABLE 17.7 (continued). NATURAL SINES (COSINES) AND TANGENTS

To obtain cosine use the formula $\cos x^{\circ} = \sin (90 - x)^{\circ}$

17.8. BERNOULLI AND EULER NUMBERS

The Bernoulli numbers \boldsymbol{B}_n and Euler numbers \boldsymbol{E}_n of order 1, of Table 17.8 are defined by

$$\frac{t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \, \frac{t^n}{n!}$$

$$\left(\frac{2}{e^t + e^{-t}}\right) = \text{Sech } t = \sum_{n=0}^{\infty} E_n \frac{t^n}{n!}$$

Note that for odd values of n both B_n and E_n are equal to zero, excluding of course B_1 which is equal to $-\frac{1}{2}$. The values of the first few numbers are

n		0	1.	-2	4.	6	8	10	12
B_n	•	1	$-\frac{1}{2}$	1 6.	$-\frac{1}{30}$	$\frac{1}{42}$	$-\frac{1}{30}$	$\frac{5}{66}$	691 2730
E_n	•	1	0	-1.	5	-61	1385	-50521	270265

Computing the sum of integral powers of integers. The sum $S_p(N)=1^p+2^p+\ldots+N^p$ is frequently needed in statistical work. For example consider a random sample of size n drawn with replacement from a finite population of N units and let V denote the number of distinct units appearing in the sample. The expected value of 1/V can be expressed as $E(1/V)=S_{n-1}(N)/N^{-n}$. In terms of Bernoulli numbers,

$$S_p(N) = \sum_{r=0}^{p} \left[\binom{p+1}{r} B_r(N+1)^{p-r+1} \right] / (p+1)$$
. We have thus

p	$S_p(N)$
1	$N(N+1) \div 2$
2	$N(N+1)(2N+1) \div 6$
3	$N^2(N+1)^2 \div 4$
4	$N(N+1)(2N+1)(3N^2+3N-1) = 30$
5	$N^2(N+1)^2(2N^2+2N-1) \div 12$
6	$N(N+1)(2N+1)(3N^4+6N^3-3N+1) \div 42$
7	$N^{2}(N+1)^{2}(3N^{4}+6N^{3}-N^{2}-4N+2) \div 24$
8	$N(N+1)(2N+1)(5N^6+15N^5+5N^4-15N^3-N^2+9N-3) \div 90$

Note: For larger values of n, values of $|B_{2n}|$ and $|E_{2n}|$ are given correct to 9 and 10 significant digits respectively. The number in parenthesis following $|B_{2n}|$ and $|E_{2n}|$ is the power of 10 by which the given tabular quantity must be multiplied.

 $[*]B_{2n}$ is positive if n is odd and negative if n is even while E_{2n} is positive if n is even and negative if n is odd,

 \circ An asterisk and a bold figure indicate that a change has occurred in the first two figures of the mantissa, shown separately in the first column immediately following the number. Thus log 1414 = 3.150449.

To obtain natural logarithm (to base e) multiply by 2.3025851.

TABLE 18.1. LIST OF SQUARES UPTO ORDER 6×6

To select a latin square at random:

Suppose a 6×6 Latin square is required. Choose a random number from 1 to 9408 the largest key number recorded under the last square. If the random number chosen is 3436, then select square number IV, since 3486 is in the range of key numbers 3241-4320 under that square. Next permute all the rows and all the columns of the selected Latin square at random and assign the letters to the treatments also at random. For obtaining a random permutation consult Table 19.1 and 19e for introductory note. The procedure is similar for Latin squares of sizes 4×4 and 5×5 , using the key numbers recorded. For squares of higher dimension one could use one of the orthogonal squares given in Table 18.2 and permute its rows, columns and treatment numbers independently at random.

a. Description of the table

Each row of digits in Table 19.1 contains a serial number of row, and a random permutation of numers 0, 1, ..., 9 followed by 40 random digits in 40 columns arranged in sets of 4. The serial numbers of the columns of random digits are indicated in the bottom line of each page so that each random digit can be identified by a row number and a column number. There are altogether 5,000 four digited random numbers (equivalent to 10,000 two digited or 20,000 one digited random numbers). They have been compiled from a number of existing random number tables. The random numbers so compiled have been examined through standard tests of randomness. No serious lack of randomness was revealed.

In using Table 19.1 we need a starting point identified by a row and a column. There are no set rules for the choice of a starting point except that no preference is shown to particular page, row or column and the choice is made without prior inspection of the numbers themselves. Some random mechanism may be adopted for locating the starting point, specially when the random number table is repeatedly used for the selection of numbers (see sub-section f of this Chapter in this connection).

Some of the uses of Table 19.1 are given below.

b. Simple random sampling from a list

(i) A straightforward method. Suppose we have to sample 5 households from a list of 23, serially numbered 0, 1, ..., 22.

Locate a starting point of random digits and consider two adjacent columns. Read two digited numbers either upwards or downwards or diagonally and record the first five numbers that lie in 0-22. If sampling is without replacement continue reading till five distinct numbers are obtained. Suppose we start from row 135 and read downwards the two digited numbers in columns 3 and 4; the selected households are 20, 3, 1, 20, 3 if repetition is allowed and 20, 3, 1, 12, 18 without repetition.

(ii) The method of inflated range. In the above method we have to reject all numbers greater than 22, which on an average amounts to 77% of the numbers read. To reduce the number of rejections, consider the range of numbers from 0 to 23k-1 where k is chosen such that 23k is nearest to, but does not exceed, a power of 10. In the present example k=4 gives the range 0 to 91. Choosing two columns as before select the first five two digited numbers in the range 0-91. Each number chosen is replaced by the remainder after dividing by 23 to obtain a number in the range 0-22. Thus, using the same starting point as in (i) above the numbers are 80, 62, 63, 25, 53 which give the sample 11, 16, 17, 2, 7.

Alternatively when k is small as in the present example the number chosen could be divided by k and the quotient taken as the number finally selected. Thus in the example considered above, the numbers 80, 62, 63, 25 and 53 on division by k = 4, lead to the sample 20, 15, 15, 6 and 13.

(iii) Independent choice of the first digit. The method of inflated range reduces the rejection of random numbers at the expense of a tedious operation of repeated division by a given number. An alternative method due to Matthai is as follows.

To select five numbers at random from 0 to 383, locate a starting point and record two digited numbers (one less than the number of digits in the given number). To each of these numbers prefix a digit at random from 0 to 3. This could be done, for example, by considering the first number from among 0 to 3 in the random permutation that appears in the same row. A three digited number, so obtained, is rejected if it exceeds 383. Thus with the columns 9 and 10 from row 271 as the starting point and reading downwords the numbers selected are as follows: 053, 295, 000, 195, 334 where in, the digits underlined are prefixed as indicated.

This method is also useful when for example one has to select numbers in the range 3845-8962. Here one selects a three digited number at random to which is prefixed a digit chosen in the range 3-8. The random permutation in the row could be used to select a random number in the range 3-8. The number finally obtained is accepted if it falls in the range 3845-8962. Otherwise it is rejected and another number is drawn in the same way.

c. Sampling with probabilities proportional to size (pps)

(i) The method of cumulated totals. Select five villages from a list of 23 with probabilities proportional to size of the village

	serial no of village		size		cumulated totals (c.t.)
<u> </u>	1		19	: :	19
		·	207		226
	.2		72		298
	3		72	· .	200
	•				
	•		•	•	
	•			٠.	883
	22		28		
	23		120		1003

Select five random numbers from I to 1003 (the last c.t.). If a chosen number is greater than the c.t. for village i and less than or equal to the c.t. for village (i+1), then the village selected is (i+1). Thus if the first random number chosen is (27), the village selected is 3. Similarly the villages corresponding to the second and subsequent random numbers are determined.

(ii) A two stage selection method. This is useful particularly when the sizes are not numerically specified nor is it intended to determine all of them beforehand, for example, in selecting crop plots with probability proportional to area etc. The method, however, requires the prior knowledge of a number S which equals or exceeds the largest of the sizes. Let 210 be that number in the above example. The procedure due to Hajek and Lahiri is as follows.

Select a number x at random from 1 to 23 and another number y from 1 to S=210. If the size of village x is $\leqslant y$ then village x is chosen; otherwise, the pair of selected numbers (x,y) is rejected and another pair is considered. If a sample of 5 is required the above procedure is continued till 5 villages get selected. This method involves rejection of a large number of selected pairs if the sizes of the villages are very disproportionate. In such cases a large village may have to be split into smaller units with smaller sizes (adding upto the size of the village). Each such unit is given a separate serial number. The original village is selected if any one of its constituent units gets selected in the process.

(iii) Cluster sampling. Draw a cluster of four villages with probability proportional to sum of the sizes.

One method is to list all the $\binom{23}{4}$ = 8855 possible clusters and their sizes. The size of any cluster is equal to the sum of the sizes of the four villages in it. Now choose a cluster with probability proportional to size by the method described in (i) or (ii) of 19c. A simpler technique is, however, to draw one village from 1 to 23 with probability proportional to size and three villages at random with equal probability and without replacement from the remaining 22.

(iv) Simple random sampling from separate lists. Select a household from six streets containing 17, 32, 28, 47, 56 and 12 houses respectively.

One method is to make a serial listing of all the 192 households and select the required number in the usual way. An alternative method is to select a number from 1 to 6 specifying a street, and another number from 1 to 56 (56 being the maximum number of households in a street) specifying a household on the street. If there is no household corresponding to the second number in the selected street the pair of selected numbers is rejected and another pair is considered.

d. Model sampling

- (i) Uniform distribution over the interval (0, 1): R(0, 1). To draw a random observation from the uniform distribution over (0, 1), start with a decimal point and record the digits in the sequence read from the random number table. The number of digits to be retained is determined by the accuracy needed in the observation. Thus selecting the 30th row and 4th column as the starting point and reading the digits horizontally, the observation is 0.04100526. The observation correct to 4 places is 0.0410.
- (ii) Discrete distribution. This is a special case of sampling with varying probabilities (see 19c) where the number of elements may be finite or infinite. Let the discrete variable X take the values $0, 1, 2, \ldots$ with probabilities p_0, p_1, p_2, \ldots . First draw an observation u from the uniform distribution R(0, 1) as indicated in (i) above. Then determine x such that

$$p_0 + p_1 + \dots p_{x-1} < u \ll p_0 + p_1 + \dots + p_x$$

The number x constitutes a random observation on X.

Continuous distributions with cumulative distribution function (cdf), F(x). Let u be a random observation from the uniform distribution R(0, 1). The value of x for which F(x) = u provides a random observation from the continuous distribution with cdf F(x). In the absence of a table of the inverse function F^{-1} , this will require inverse interpolation in a table of F(x).

Thus, suppose a random observation is to be drawn from the Cauchy distribution with cdf

$$F(x) = \frac{1}{10\pi} \int_{-\infty}^{x} \frac{dt}{1 + (t - 15)^{2}/100} = \frac{1}{\pi} \left[\tan^{-1} \left(\frac{x - 15}{10} \right) + \frac{\pi}{2} \right]$$

Given u, x is determined by the equation $x = 15 + 10 \tan \theta$ where $\theta = \pi(u - 0.5)$ radians = (180u-90) degrees. If u = 0.2537 the corresponding x as obtained from Table 17.7 is given by $15+10\times0.9770=24.77$.

(iv) Bivariate distribution of the variables X, Y with cdf F(x, y). Let the cdf of the marginal distribution of X be denoted by $F_i(x)$ and of the conditional distribution of Y given X = x by $F_2(y|x)$. A random observation of X, Y is given by x, y where x and y are independent observations from $F_1(x)$ and $F_2(y \mid x)$ respectively chosen in the manner described in (i) to (iii) above.

Thus, suppose a random observation (x, y) is to be drawn from the bivariate normal distribution with the specifications: mean X=50, mean Y=75, variance $X = 100 = (10)^2$, variance $Y = 225 = (15)^2$ and correlation Note that marginally X is normal with mean 50 and variance 100 and conditionally. given X = x, Y is normal with

mean:

$$75 + \frac{0.6 \times 15}{10} (x - 50) = 30 + 0.9x$$

and variance:

$$225[1-(0.6)^2] = 144 = (12)^2$$
.

The problem reduces to that of drawing an observation x from N (50, 10) and then an observation y from N (30+0.9x, 12) which can be done by the procedure explained in (iii) above. To get x, take an observation u from R(0, 1) as explained in (i). If u = 0.3135, the corresponding standard normal deviate obtained from Table 3.1 by inverse interpolation, is -0.4860. Hence

$$\frac{x-50}{10} = -0.4860 \quad \text{or} \quad x = 45.140$$

Similarly if v = 0.5912 is an independent observation from R(0, 1) with the corresponding standard normal deviate 0.2306, then

$$\frac{y - 30 - 0.9x}{12} = \frac{y - 30 - 40.626}{12} = 0.2306 \quad \text{or} \quad y = 73.393$$

The procedure can be extended to the multivariate normal case with dispersion matrix Σ and mean vector μ .

An alternative and simpler procedure in the special case of the multivariate normal distribution is as follows. First find a matrix A such that $\Sigma = AA'$. If $y' = (y_1, y_2, ..., y_p)$ are p independent observations drawn from N(0, 1) as illustrated in (iii) then the observations for the specified multivariate distribution is

$x = Ay + \mu$

e. To obtain a random permutation of n digits (elements)

(i) For $n \leqslant 10$ by using the random permutations given in Table 19.1

Example: To obtain a random permutation of numbers 1-8 or equivalently of eight letters (symbols) a, b, c, ..., h.

Choose a serial number at random from 1 to 500 (rows) and select from Table 19.1 the permutation corresponding to the selected row number. Thus if the serial number chosen at random is 232, the permutation to be selected is 5071389264. From this we obtain the permutation of any subset of numbers by omitting the others. In the present problem deleting 0 and 9 we obtain the permutation 57138264 of numbers 1–8.

(ii) For n > 10 using random permutations of Table 19.1

Example 1: To permute numbers 0-12 at random. A random permutation of 0-9 is selected as in (i) above. The positions of numbers 0, 1, ..., 9 are determined by such a selection. We then determine the positions of 10, 11, 12 successively choosing one number at a time. For 10, there are 11 possible positions. It could occur either at the extremities of the selected permutation or in any one of the 9 gaps in between two smaller numbers. The eleven positions could be serially numbered 1-11 and the position of number 10 decided by selecting a number at random from 1-11. Number 11 could then be fitted in an exactly similar manner in one of the 12 possible positions and so on.

Example 2: To permute numbers 0-17 at random. One possibility is to repeat the process explained in Example 1, several times, and adding the numbers 10, 11, ... 17 in any succession. A variation of this method is suggested below. The eighteen numbers are divided at random into two sets of nearly equal numbers. This can be easily done by matching the given numbers with the digits in any column of the random number table and taking all the numbers matched with even digits as belonging to the left set and the rest to the right set. If the number in any set exceeds ten, this may be further divided into two sets, the left and right subsets being determined as above. We thus have a number of sets which are already randomly ordered and each of which contains less than 10 numbers. The relative positions of the numbers within each set are determined by permuting these numbers, using the methods in (i) above, independently for each set.

The division of the given numbers into sets may not be a simple operation. We suggest the following general method which uses the random digits of Table 19.1 but not the random permutation of numbers listed in the table.

(ii) For n > 10 using a table of random numbers

Example: To permute numbers 1-84 at random. One method is to consider two columns of random numbers and note the numbers in the order in which they occur omitting repetitions and the numbers exceeding 84.

A variation of this method due to Rao, which does not omit any number read from the random number table is as follows.

Locate a starting point consisting of a row and two columns of random digits of Table 19.1 for reading two digited numbers. Each number defines a cell in a 10×10 two way table, corresponding to the values of the first and second digits. We put 1 in the cell corresponding to the first number, 2 in the cell of the second number and so on upto 84, as we read the two digited random numbers in the sequence as they occur. The numbers in the cells read out in the order, from left to right in each row and then in the next row and so on, provide a random permutation. If in any particular cell there is more than one number these could be randomly permuted within the cell. The first five numbers corresponding to the random numbers 31, 17, 81, 45, 31... are entered in the chart below to illustrate the method.

second digit

		0	1	2	3	4	5	6	7	8	9
	0										
	1								2		
	2				,						
,	3		(1, 5)			,					
first	4						4				
digit	5			·							
	6			-							
	7										
	8		3								
	9										

As it stands we obtain a permutation of numbers 1-5.

where (1, 5) has to be replaced by a random permutation of the two numbers which can be easily done.

f. Generation of random numbers by coin tossing

This method comes in handy when a random number table is not available. It can also be used to locate a random start in a table of random numbers.

The procedure with an unbiased coin is to toss it a number of times, observe the sequence of heads and tails, and compute a number based on this sequence. A number so obtained is a random number in a certain range. The number of tosses needed to cover a certain range of numbers and the method of conversion of a sequence of heads or tails to a number on a decimal scale are as explained below. Suppose that it is desired, to choose a random number in the range 1-500. First determine the smallest integer k such that $2^k \ge 500$. In this example k = 9. Then, toss an unbiased coin k times. Let the observed sequence of heads (1) and tails (0) be

A random number is then obtained by finding the decimal equivalent of the binary sequence and adding 1 to it.

The number corresponding to above sequence (or a binary number) is $0 \times 2^8 + 0 \times 2^7 + 1 \times 2^6 + 0 \times 2^5 + 1 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + 1 \times 2 + 0 \times 2^0 = 94$ giving the random number 94 + 1 = 95.

If the number so obtained is 501 or more, it is rejected and fresh tosses are made. Powers of 2 needed for conversion of sequences to numbers have been given in Table 17.5 (powers of two).

The random number table has 40 columns (on each page) and 500 rows. It is suggested that a random start specified by a row and a column be used in reading the numbers. For this purpose we have to find two numbers one in the range 1-500 representing the rows and another in the range 1-40 representing the columns. The method of generating a random number in the range I-500 by coin tossing is already explained. To select a random number in the range 1-40, we first choose a number in the range 1-64, which requires 6 tosses, conversion of a six digited binary number and addition of 1 as explained above. If the number chosen is within the range 1-40 it is accepted. If it exceeds 40, it is rejected and the procedure is repeated. This procedure incidentally leads to about 40% rejections. Rejections could be minimised in the following way. If the number obtained exceeds 40 compute its difference (y) from 40. Toss the coin once more and record the result x of toss which is either 0 The selected random number is 24x+y. The number so obtained (tail) or I (head) will always lie in the range 1-48; it is rejected if it exceeds 40, in which case a fresh set of 6 tosses are made and the entire procedure is repeated.

RANDOM NUMBERS AND PERMUTATIONS

12 ounces = 1 pound		
* 1 :	short ton (USA) = 2000 por	ands (av.) = 2 kips

[†] The grain is the same whether it is avoirdupois, troy or apothecaries' weight.

l knot (international) = 101.269 ft/min. = 1.68781 ft/sec. = 1.15078 miles/hr.

1 micron = 10^{-3} mm.

Ionic (electronic) charge (e) = 4.80×10^{-10} E.S.U. Mass of electron (m₀) = 9.1085×10^{-28} g.

Mass of hydrogen atom = 1.673×10^{-24} g.

Gas constant (R) = 8.3170×10^7 erg/degree/gram mole (physical scale) = 8.315×10^7 (chemical scale).

Avogadro's number = 6.02486×10^{23} per gram mole (physical scale) = 6.02332×10^{23} (chemical scale).

Planck's constant (h) = 6.62517×10^{-27} erg-sec. Boltzmann constant (k) = 1.38044×10^{-26} erg/degree.

Density of Mercury at 0°C = 13.5955 g/cu cm. Density of water, maximum at 3.98°C = 0.999973 g/cu cm. Density of air, 0°C and 760 mm pressure = 1.2929 g/l.

Velocity of sound in dry air, 0°C = 331.36 m/sec. = 1087.1 ft/sec.

Velocity of light in vacuum = 2.997929×10^{10} cm/sec.

Heat of fusion of water at 0°C = 79.71 cal./g. Heat of vapourisation of water at 100°C = 539.55 cal./g.

Electrochemical equivalent of silver = 0.001113 g/sec. international ampere.

Absolute wave length of red cadmium light in air, 15°C, 760 mm pressure, = 6438.4696 angstrom units.

Wave length of orange-red line of krypton, 86 = 6057.802 Å.

Decibel is a measure of sound intensity in logarithmic scale. Zero decibel loudness level corresponds to an intensity (J₀) of 10⁻¹⁶ Watt/sq cm or 10⁻⁸ erg/cm²/sec. An intensity J expressed in decibel units is $10 \log_{10} (J/J_0)$.

Physical Constants

The Earth

Polar radius = 6357 km = 3951 miles, Equartorial radius = 6378 km = 3964 miles

Mean radius = 6371 km = 3960 miles

Flattening = 0.003367

Circumference = 24,920 miles

1° of latitude at equator = 110.5 km = 68.70 miles

 1° of latitude at poles = 111.7 km = 69.41 miles

1° of longitude at equator = 111.3 km = 69.17 miles

Inclination of equator to ecliptic = 23°27'

Surface area = $5.101 \times 10^8 \text{ km}^2$, Volume = $1.083 \times 10^{12} \text{ km}^3$

Mass = 5.980×10^{27} g = 6.586×10^{21} tons, Mean density = 5.520 g/cm³

Ratio of mass of sun to earth = 333,432:1

Ratio of mass of earth to moon = 81.45:1

Mean distance to sun = 1.497×10^{13} cm = 9.300×10^{17} miles

Distance of sun at perihelion = 1.47×10^{13} cm = 9.136×10^{7} miles

Distance of sun at aphelion = 1.52×10^{13} cm = 9.447×10^{7} miles

Mean distance to moon = 3.847×10^{10} cm = 2.391×10^{5} miles

Number of satellites = 1 (moon)

Greatest height (Mt. Everest) = 29028 ft.

Greatest depth (Challenger Deep) Mariana trench = 35,800 ft.

Lowest on land (Dead sea) = 1286 ft.

Land area = $148.8 \times 10^6 \text{ km}^2 = 5.747 \times 10^7 \text{ miles}^2$, Ocean area = $361.3 \times 10^6 \text{ km}^2 = 13.95 \times 10^7 \text{ miles}^2$

Acceleration of gravity (g) in cm per sec per sec. at latitude λ and height (h) (in metres) above sea level $g = 980.616 - 2.5928 \cos^2(2\lambda + 0.0069) (\cos^2(2\lambda)^2 - 0.0003) h$.

Value of g for $\lambda = 45^{\circ}$ at sea level = 980.621 cm per sec. per sec. = 32.173 ft. per sec. per sec.

Solar energy incident on unit area at right angles to sun's rays at the earth's mean distance per unit time = 2.00 Calories/cm²/minute.

Age of the earth = Between 4×10^9 and 5×10^9 years

Nearest star (Proxima Centauri) = 4.31 light years

Revolution = 365.256 days, Rotation = 23 hr. 56 min. 4.09 sec.

Rotational velocity of earth at equator = 460 m/s.

Length of seconds pendulum at sea level, latitude 45° = 99.3577 cm = 39.1171 in.

Population in millions (year in brackets): 1550 (1900), 1907 (1925), 2497 (1950); projections: 3828 (1975), 6267 (2000).

Astronomical Data on Time

- I sidereal day = 86164.0906 mean solar seconds
- I tropical (civil) year = 365.2422 mean solar days, I sidereal year = 365.2564 mean solar days
- 1 anomalistic year = 365.2596 mean solar days
- 1 synodical month = 29.53059 mean solar days, 1 tropical month = 27.32158 mean solar days, 1 sidereal month = 27.32166 mean solar days.

4. THE POISSON DISTRIBUTION

4.1. INDIVIDUAL TERMS

- 1. Table 4.1 gives values of $p(x, \lambda) = e^{-\lambda} \lambda^x/x!$, x = 0, 1, 2, ... for $\lambda = 0.1$ (0.1) 1.0, 1.5, 2.0 (1.0) 10.0. The values are correct to eight places of decimal for λ upto 5.0 and to seven places of decimal for $\lambda = 6.0$ to 10.0.
- 2. For purposes of $(\lambda$ -wise) interpolation between the tabulated values the following formula based on Taylor expansion will be found useful. Let the value of $p(x, \lambda)$ be required for a given λ and λ_0 stand for the tabular argument closest to λ . Write $d = \lambda \lambda_0$. Then,

$$p(x, \lambda) = p(x, \lambda_0) - d\Delta_x \ p(x-1, \lambda_0) + \frac{d^2}{2!} \ \Delta_x^2 \ p(x-2, \lambda_0) + \dots$$
$$+ (-1)^k \frac{d^k}{k!} \Delta_x^k \ p(x-k, \lambda_0) + R.$$

where Δ_x , Δ_x^2 , ... are the 1st, 2nd, ... order differences taken with respect to x, and $R = \frac{d^{k+1}}{(k+1)!} \Delta_x^{k+1} p(x-k-1, \lambda^*)$, where λ^* is some value lying between λ_0 and λ . It will thus be possible by inspection of the tabulated values to judge the maximum possible magnitude for the error R.

Example $\lambda = 5.25$, x = 3.

ROMAN AND HINDI NUMERALS

a. Roman numerals

The system invented by the early Romans about 2000 years ago was widely used by the people of Europe until about the 16th century. Roman numerals are still used on clocks and monuments, to show chapters of a book, and for volume numbers of some journals.

The Roman system is built on the base of ten and uses the symbols:

I=1, V=5, X=10, L=50, C=100, D=500, M=1000. The first twenty numbers are as follows:

$$I = 1$$
 $VI = 6$ $XI = 11$ $XVI = 16$
 $II = 2$ $VII = 7$ $XII = 12$ $XVII = 17$
 $III = 3$ $VIII = 8$ $XIII = 13$ $XVIII = 18$
 $IV = 4$ $IX = 9$ $XIV = 14$ $XIX = 19$
 $V = 5$ $X = 10$ $XV = 15$ $XX = 20$

There are two rules of writing numbers. (1) If a letter or a set of letters is placed before a letter of higher value, it is to be subtracted from the latter. Thus IV = 4, XC = 90. (2) If a letter of smaller value is placed after one of larger value it is to be added. Thus LX = 60, LV = 55. The Romans first read the thousands, then the tens, then the ones. To read numbers, sometimes one counts, as in counting III, sometimes subtracts, as in finding the value of IV, sometimes adds as in finding the value of XVIII. Thus

MCM XX = 1,920, CCCXLVI =
$$346$$

MDC XXXVIII = 1,638, MMMM = 4,000

A line drawn above a group of letters multiplies the number by one thousand. Thus $\overline{\text{MDC XXXVIII}} = 1,638,000.$

b. Devanagari (Hindi) numerals

magari (Hundi) hamiltonian
$$0 = 0$$
, $0 = 1$, $0 = 2$, $0 = 3$, $0 = 3$, $0 = 4$, $0 = 5$, $0 = 7$, $0 = 7$, $0 = 8$, $0 = 9$.

	99)	96	v1	97		99		96		97		99		

^{1.} Code number of the year 2000 is VI.

^{2.} A leap year is one which is divisible by 4, except that in the case of a century it should be divisible by 400. Thus 1900 is not a leap year but 2000 is.

^{3.} The code numbers are based on the Gregorian calendar which was first adopted in 1582.

^{4.} Leap years are printed in bold face.

PERPETUAL CALENDAR (GREGORIAN)

NON LEAP		CO	LEAP					
YEAR	I	П	Ш	IV	V	VI	VII	YEAR
	·		Doys	of the	Veek			
APR, JULY	Su	M	${f T}$	\mathbf{W}	Th	E	Sa	SEP, DEC

AUG	W	Th	F	Sa	Su	M	Ť	MAY
FEB, MAR, NOV	Th	F	Sa	Su	M	T	W	FEB, AUG
JUNE	F	Sa	Su	M	T	W	Th	MAR, NOV
SEP, DEC	Sa	Su	M	T	W	Th	F	JUNE
	1	2	3	4	5	6	7.	
	8	9	10	11	12	13	14	
	15	16	17	18	19	20	21	
	22	23	24	25	26	27	28	
	29	30	31					

To find the calendar for a given year and month there are three steps.

- (1) Find the code number of the given year from the previous page.
- (2) If it is a Leap year (in bold) use the months on the right; if not, the months on the left of the above Table. Read the day of the week corresponding to the given month and code number of given year as found in (1).
- (3) Observe that there are 7 rows of the days of the week. Choose that row beginning with the day of the week as determined in (2). This row together with the bottom portion of the Table containing the dates from 1 to 31 provides the calendar for the given month and year.

Hold the index fingure of the left hand against the chosen row (of the days of the week) and read the day of the week corresponding to any given date.

Example: What day of the week was June 29, 1893?

Code number of 1893 is VII. Using the months for a nonleap year, the day of the week for June and year code VII is Th (Thursday). Then using the row beginning with (Th) we find that 29th was Thursday.

Verify that 10 September 1632 was Friday.
